#### ABSTRACT

This report uses the 1979-1996 National Household Surveys on Drug Abuse to investigate the role of parents, especially members of the baby boom generation, on the marijuana use of children. The association of marijuana use between parents and children, the differences among parental birth cohorts, and the determinants of child marijuana use are investigated. Five major research goals are addressed: develop a strategy to define parental exposure to the marijuana epidemic; assess the strength of the association between parental and child marijuana use according to pattern and extensiveness of use, by sex of parent, and age, sex and ethnicity of child; assess the impact of membership in the baby boom generation and parental exposure to the marijuana epidemic on child marijuana use; determine the unique influence of parental marijuana use on the child's marijuana use; identify important predictors of marijuana use by young people in addition to parental marijuana use. The report addresses the research goals outlined above through descriptive and multivariate analyses. The Technical Appendix provides details about the construction of the drug use and other selected variables. Appendix tables present survey-specific data for the multiple surveys that are aggregated in most of the tables presented in the main body of the report. (Contains approximately 76 references, 50 tables, and 15 figures.) (GCP)

### Substance Abuse and Mental Health Services Administration Office of Applied Studies

The Office of Applied Studies (OAS) serves as a focal point for data collection, analyses, and dissemination activities on the incidence and prevalence of substance abuse, the distribution and characteristics of substance abuse treatment facilities and services, and the costs and outcomes of substance abuse treatment programs. Three major surveys provide information used by OAS:

- National Household Survey on Drug Abuse (NHSDA). The NHSDA provides information on the prevalence of substance abuse and perceptions of risk in the population, and the sociodemographic characteristics, criminal, and other behavioral activities of individuals with a substance abuse problem. In 1999, the NHSDA sample increased from 25,000 to 70,000 so as to generate State level estimates of substance abuse prevalence.
- Drug Abuse Warning Network (DAWN). The DAWN obtains information on drug-related admissions to emergency departments and drug-related deaths identified by medical examiners.
- Drug and Alcohol Services Information System (DASIS). The DASIS consists of three data sets (I-SATS, N-SSATS, and TEDS) developed with State governments. These data collection efforts provide national and State level information on the substance abuse treatment system.

# **Office of Applied Studies Web Site Substance Abuse and Mental Health Statistics**

www.DrugAbuseStatistics.samhsa.gov

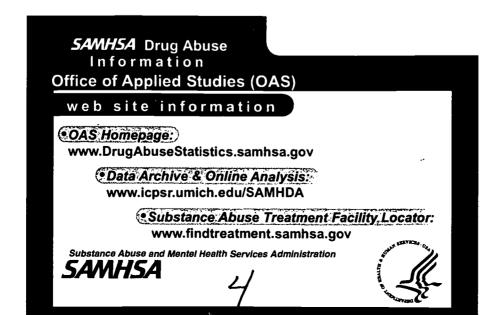

The Substance Abuse and Mental Health Services Administration (SAMHSA), Office of Applied Studies (OAS) Web site contains highlights from the latest OAS report, data on specific drugs of abuse, and publications of alcohol, tobacco, and illegal drug use. The Web site also contains some data that have not been published, such as detailed tables from the NHSDA and DAWN. The OAS publication series include information from:

- National surveys of households (NHSDA)
- Substance abuse treatment facilities (DASIS)
- Emergency departments and medical examiners (DAWN)
- Methodological studies
- Analysis of special SAMHSA topics

In addition to finding reports on the Web site, you can:

- Locate a drug or alcoholism treatment facility
- Conduct data analysis online (SAMHDA)
- Download public use files
- Submit OAS publication requests
- Join the OAS mailing list
- Find answers to frequently asked questions (FAQ) about OAS data

SAMHSA's OAS Web site contains the **Substance Abuse Treatment** Facility Locator, a searchable online version of the National Directory of Drug and Alcohol Abuse Treatment Programs. This version also produces maps with the location of the facilities you have listed.

### **HIGHLIGHTS**

### Purpose and Nature of the Report

- Following a steady decline in the use of marijuana by young people in the US throughout the 1980s, use increased sharply beginning in the early 1990s. The causes for this increase remain to be understood.
- This report had two major aims: 1) A major aim was to test the hypothesis that the increase in marijuana use by recent generations of young people was due to the fact that their parents were members of the baby boom generation. These parents belonged to cohorts who became heavily involved in using marijuana, and who, because of their adolescent experience, may have unintentionally facilitated the use of marijuana by their children. 2) A second aim was to assess the extent of parental influence on children's marijuana use, irrespective of membership in the baby boom cohorts.
- The analyses took advantage of the inclusion of multiple respondents per household in the National Household Surveys on Drug Abuse, a series of repeated national cross-sectional surveys of the population aged 12 and older. Clustering provided samples of parent and child dyads drawn from the same households.
- The analyses were based on 9,463 dyads composed of one parent (mother or father) and one child aged 12 to 25 per household from 10 surveys conducted from 1979 to 1996.
- Descriptive, multivariate logistic regression analyses, and a limited number of structural equation models were estimated.
- Five periods of the marijuana epidemic from 1963 to 1996 were identified in terms of marijuana use incidence and prevalence. Birth cohorts were characterized by type of exposure to the epidemic experienced at ages 15-18, the years of highest risk for involvement in marijuana. Nine groups of cohorts with different types of exposure were identified.
- Based on drug use reports provided independently by parents and children, the association in marijuana use between parents and children was assessed as a function of parental exposure to different periods of the marijuana epidemic.
- Predictors of the children's marijuana use other than parental marijuana use and parental birth cohort were also examined. These factors included sociodemographic characteristics, behavioral and attitudinal characteristics of parent and child, including parental use of drugs other than marijuana, and parent and child marijuana related attitudes and delinquency.

#### Results

- Parental membership in the baby boom generation (1946-1964 birth cohorts) did not account for the differential rates of children's marijuana use.
- Lifetime marijuana use rates among parents of youths and young adults approximately doubled from 1979 to 1994, reflecting the increasing dominance of the baby boom cohort among parents. However, most of this increase occurred during the 1980's, a period in which youth and young adult drug use rates were declining.
- During the period of rapid increase in youth marijuana use (1992 to 1995), the percent of parents who were baby boomers or who had ever used marijuana did not change enough to have been a major factor in the youth increase.
- Parental lifetime and last year marijuana use increased the risk that a child would ever use marijuana. Controlling for parent and child sociodemographic characteristics, the children of parents who ever used marijuana were about three times as likely to have ever used marijuana as the children of parents who never used the drug. With additional control for attitudinal and behavioral characteristics, the risk declined to about two.
- Parents who stopped using marijuana and those who were currently using marijuana had children who used marijuana at similar rates. This suggests that parental influence does not reflect imitation of the parent by the child but the effect of the parent having chosen to become a marijuana user.
- The influence of parental marijuana use on child lifetime marijuana use was similar for mothers and fathers, and sons and daughters.
- Parental influence on child marijuana use did not vary among racial/ethnic groups, after controlling for parent and child characteristics.
- Parental use of cigarettes, alcohol and cocaine each independently increased the risk that a child will use marijuana over and beyond the influence of parental use of marijuana.
- Parents who perceived little risk associated with marijuana use had children with similar beliefs. In addition, parental attitudes had an indirect effect on the child's use through the child's own attitudes.
- Adolescent attitudes had the strongest association with adolescent marijuana use of any of the three adolescent characteristics that were examined. Adolescents who perceived no risk or slight risk in occasional marijuana were twelve times more likely to have used marijuana in the last year than adolescents who perceived great risk.
- The association between adolescent marijuana use and attitudes about the lack of harm associated with marijuana use was five times as strong as the association between adolescent and parental use.

Å

χv

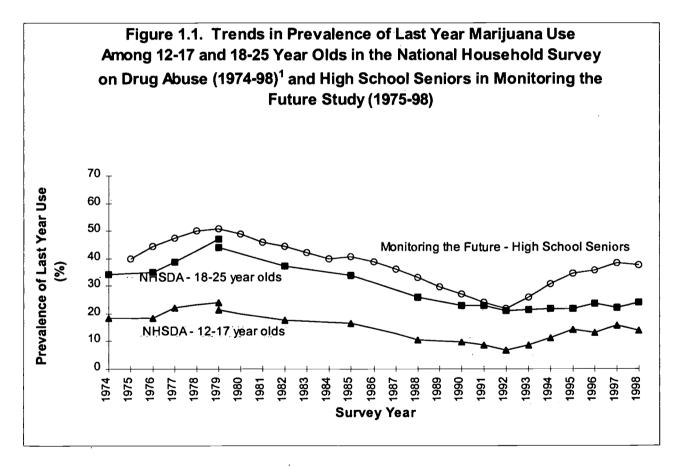

- Adolescent delinquency had a strong association with adolescent marijuana use and attitudes about the lack of harm associated with marijuana use.
- The association between adolescent delinquency and marijuana use was four times as strong as the association between adolescent and parental use.
- Adolescents who dropped out of school were significantly more likely to use marijuana than non-dropouts.
- Externalizing behavioral problems (e.g., aggression, delinquency) were more strongly associated with adolescent marijuana use than were internalizing problems (e.g., anxiety, depression).
- Sociodemographic characteristics, including ethnicity, parental education and marital status, were weakly associated with adolescent marijuana use.

### CHAPTER 1: INTRODUCTION

#### 1.1 Adolescent Use and Parental Influences

The increase in marijuana use by adolescents, particularly young teens, during the nineties (SAMHSA, 1998a, b; 1999; Johnston et al., 1998) is striking and remains to be understood. Following a steady decline from the high prevalence levels observed in the late seventies, sharp increases beginning in 1993 through 1997 were observed among young people, especially adolescents (see Figure 1.1). A slight decline has been observed among adolescents between 1997 and 1998. Among youths aged 12-17 in the United States, the annual use of marijuana reached a high of 21.3% in 1979, decreased to a low of 6.9% in 1992, increased to 15.8% in 1997, and was 14.1% in 1998 (SAMHSA 2000).

<sup>&</sup>lt;sup>1</sup> Estimates for 1979 through 1993 were adjusted for changes in question format as of 1994.

Sources: SAMHSA (1991; 1998b); University of Michigan.

Several explanations for the increase have been proposed: the coming of age of a new generation of youths who have had little direct exposure to the negative consequences of drug use in an era of declining drug use (Bachman, et al., 1998); a decrease in drug prevention efforts; and reduced governmental and media attention to the drug problem. Another relevant factor

might be the influence of parents who, as members of the baby boom generation, belonged to cohorts heavily involved in marijuana use in their own youth. Because of their cultural and historical experiences in adolescence, these parents may be more likely to have children who use marijuana themselves.

Various individual and social factors have been related to drug use by young people. Individual factors include unconventional attitudes, lack of religiosity, inadequate school performance, and poor relationships with parents (Hawkins et al., 1992). Drug use in the immediate social environment of young person, especially drug use by peers, has consistently been identified as a most important factor (Bailey and Hubbard, 1991; Bauman and Fisher, 1986; Dishion and Loeber, 1985; Flay et al., 1994; Hawkins et al., 1992; Iannotti and Bush, 1992; Kandel, 1980; Urberg et al., 1990). Drug use by parents has also been found to be related to and to predict drug use by adolescents. Moreover, the influence of parents relative to the influence of peers may be stronger than is generally thought. Because of methodological issues, the influence of peer drug use relative to the influence of parental use may have been overestimated by as much as a factor of five (Kandel, 1996).

Relatively few studies have examined the impact of parental marijuana use on child use. To the best of our knowledge, we have identified eight studies. Most were conducted more than a decade ago and are about evenly divided among those that relied on perceived parental behavior (Fisher et al., 1987; Forster, 1984; Huba and Bentler, 1980; Johnson et al., 1984; Newcomb and Bentler, 1986) and independent parental reports of their marijuana use (Andrews et al., 1993; Brook et al., 1985; Gfroerer, 1987; Hops et al., 1996; Kandel, 1974; Kandel and Andrews, 1987). One study examined both types of reports (Newcomb et al., 1983). Parental effects of marijuana use have been documented for mothers and fathers, sons and daughters, with no differences by parent or child gender (Gfroerer, 1987; Hops et al., 1996; Huba and Bentler, 1980; Kandel, 1974; Kandel and Andrews, 1983; Newcomb et al., 1983). Only one study (Newcomb and Bentler, 1986) examined the association between perceived parental use and self-reported child marijuana use as a function of ethnicity. The association was stronger among whites and Hispanics than African-Americans. Similarity between parents and children in drug use has also been documented on the basis of independent reports from each respondent for the use of cigarettes (Kandel and Wu, 1995; Bauman et al., 1990; Gfroerer, 1987; Needle et al., 1986; Rittenhouse and Miller, 1984), alcohol (Barnes et al., 1986; Gfroerer, 1987; Green et al., 1991; Lau et al., 1990), and cocaine (Gfroerer, 1987). Gender and ethnic patterns of association with these other substances differ from those observed with respect to marijuana. Maternal influence for smoking appears to be more powerful than paternal influence (Kandel, 1974; Kandel and Wu, 1995). particularly among daughters (Charlton and Blair, 1989; Chassin et al., 1986; Clayton, 1991; Kandel and Wu, 1995). A sex-specific impact of parental alcohol use has been reported, particularly for sons (Cadoret et al., 1980; Cloninger et al., 1981) and to a lesser extent for daughters (Bohman et al., 1981). The influence of parental smoking on child cigarette smoking is greater among white than African-Americans and Hispanics (Griesler and Kandel, 1998; Sussman et al., 1987).

The National Household Survey on Drug Abuse (NHSDA) provides an unusual opportunity for investigating parental influences on children's marijuana use, particularly as a function of parental membership in the baby boom generation. In a number of households, up to two respondents were selected for participation in the surveys. In most of these households, one respondent was an adult, providing independent data on parental patterns of drug use in dyads of parents and children. The multiple surveys spanning close to a twenty-year interval provide variations in the adolescent drug experiences of parents, variations in the historical context of the parents' adolescent experiences, and variations in the historical periods in which the children reached developmental periods of risk for initiation into marijuana use.

Two earlier analyses of parent-child associations in drug behavior were conducted on the NHSDA. In analyses of parent-child pairs in the 1974, 1976 and 1977 surveys, Rittenhouse and Miller (1984) found that current maternal cigarette smoking and alcohol use were significantly associated with child lifetime and current marijuana use. Paternal cigarette smoking and alcohol use had no impact on youth substance use. Parental marijuana use was not examined. In subsequent analysis of dyads in the 1979 and 1982 surveys, Gfroerer (1987) examined same- and cross-drug associations for parent and child cigarette, alcohol, marijuana and cocaine use. Many more significant associations in substance use occurred for mothers than fathers. Although parental use of all classes of substances was associated with child marijuana use, the lifetime use of marijuana by mothers and fathers was strongly and uniquely associated with child lifetime and current marijuana use, controlling for sociodemographic characteristics and parental current cigarette smoking and alcohol use. The association between parental and child drug use was stronger for marijuana than for cigarettes, alcohol or cocaine.

### 1.2 Aims of Report

We undertook research in the NHSDA to investigate the role of parents, especially members of the baby boom generation, on the marijuana use of children. We investigated the association of marijuana use between parents and children, the differences among parental birth cohorts, and the determinants of child marijuana use. We addressed five major research goals:

- 1) Develop a strategy to define parental exposure to the marijuana epidemic.
- 2) Assess the strength of the association between parental and child marijuana use according to pattern and extensiveness of use, by sex of parent, and age, sex and ethnicity of child.
- 3) Assess the impact of membership in the baby boom generation and parental exposure to the marijuana epidemic on child marijuana use. In particular, determine whether parents who were members of baby boom birth cohorts at the highest risk for marijuana initiation in their adolescence influence the behavior of their children differently from parents from other birth cohorts, i.e., baby boom cohorts that did not experience the explosion in marijuana use in the 1970s, or cohorts that preceded or followed the baby boom generation.

- 4) Determine the unique influence of parental marijuana use on the child's marijuana use, controlling for other determinants of the child's use, in particular, parental use of drugs other than marijuana.
- 5) Identify important predictors of marijuana use by young people in addition to parental marijuana use. This analysis is constrained by the limited data other than drug use available in the NHSDA.

This report is based on parent-child dyads available in NHSDA surveys conducted from 1979 to 1996, i.e. the 1979, 1982, 1988 and 1990-1996 surveys. Although dyadic data were ascertained in the 1974, 1976 and 1977 surveys, they are not available for analysis. Dyadic data were not collected in 1985. The report addresses the research goals outlined above through descriptive and multivariate analyses.

### 1.3 Organization of Report

Chapter 2 outlines the central hypothesis of the study. It proposes an empirical definition of exposure to the marijuana epidemic that is based on a differentiation between incidence and prevalence rates, identifies five different periods of the marijuana epidemic from 1963 to 1996 and identifies the developmental period of highest risk for onset of marijuana use. On the basis of these criteria, the chapter delineates nine groups of birth cohorts with different experiences of the epidemic in a crucial phase of adolescent development. The assessment of the impact of differential parental exposure to the marijuana epidemic on child marijuana use is presented in Chapter 6.

Chapter 3 briefly describes the NHSDA methodology and the dyadic samples available for analysis, and discusses the strengths and weaknesses of the NHSDA for achieving the aims of the research. The chapter also describes the measurement of variables used in the analysis. Complete details about the measurement and construction of the variables are presented in the Technical Appendix.

Chapter 4 presents the sociodemographic characteristics of parents and children in the dyadic sample. Characteristics of children and adults in dyads and those not in dyads are compared to assess the impact of non-systematic sampling on individuals selected for inclusion in dwelling unit pairs.

Chapter 5 reports the rates of marijuana use observed among parents and children and the associations between parent and child use through cross-tabulations and odds ratios. The chapter also includes a comparison of drug use patterns among youths and parents in dyads and those not in dyads.

Chapter 6 assesses the impact of differential parental exposure to the marijuana epidemic on children's marijuana use. The chapter also examines predictors of child marijuana use other than parental birth cohort and membership in the baby boom generation. Limited variables are available in the NHSDA data set to implement such analyses, since the content of the surveys focused almost exclusively on patterns of drug use. Two sets of multivariate analyses were

implemented. One set consisted of multivariate logistic regressions, which provided an overview of the relative importance of different factors, including parental marijuana use, on the child marijuana use. In addition to membership in the baby boom generation, parental exposure to various periods of the marijuana epidemic and parental marijuana use, the predictors included parental use of other substances (cigarettes, alcohol, cocaine), and sociodemographic, attitudinal and personality characteristics of parents and children. The second set of analyses consisted of structural causal models, which provided a more dynamic understanding of the direct and indirect effects of selected parental and child factors on the child marijuana use.

The Technical Appendix provides details about the construction of the drug use and other selected variables.

Appendix tables present survey-specific data for the multiple surveys that are aggregated in most of the tables presented in the main body of the report.

### **CHAPTER 2: EXPOSURE TO THE MARIJUANA EPIDEMIC**

### 2.1 A Basic Hypothesis

A basic hypothesis of the study was that child marijuana use would be most strongly associated with parental marijuana use among families where the parent was a member of baby boom generation cohorts that were exposed to the marijuana epidemic in adolescence. This hypothesis was based on the assumption that cultural and historical factors experienced by parents influence involvement in marijuana use by their children. This would be reflected in a greater association in marijuana use within parent-child dyads among baby boom families exposed to the marijuana epidemic than among those not exposed or in non-baby boom families. Cohorts born between 1946 and 1964 constitute the baby boom generation (Light, 1988).

An empirical test of the hypothesis required a clear definition and delineation of the marijuana epidemic, the historical period when it was manifest, and parental exposure to the epidemic in critical periods of development, when risk for marijuana initiation is the highest.

### 2.2 Definition of Exposure to the Marijuana Use Epidemic

In classical epidemiology, the beginning of an epidemic is usually conceptualized in terms of incidence rates, with the first case marking the beginning of the epidemic and exposure to it adjusted for any relevant incubation period (Kelsey, 1996). Such a criterion may not be appropriate to a drug epidemic, where modeling and socialization play important roles and may depend upon a critical mass of users. The concept of an epidemic may not even be appropriately applied to historical changes in marijuana use. While traditional epidemics may have an insidious onset, the experience of a marijuana epidemic requires an explicit awareness of patterns of behavior in society.

We considered that two features of marijuana consumption in the population may affect individuals' perceptions and experiences of cultural changes related to marijuana use: incidence, i.e., the rate of new users in the population, and prevalence, i.e., the rate of users at any particular time. We conceptualized that the adolescent experience of the marijuana epidemic involves exposure to two features of marijuana use in the population: exposure to high (or increasing) incidence rates and exposure to high prevalence rates of use, especially among young adults. High prevalence results from high incidence rates and sustained use after increases in incidence. Different parental birth cohorts were exposed to different rates of incidence and prevalence of use in their adolescence. The differentiation between incidence and prevalence constitutes a novel way of conceptualizing exposure to the marijuana epidemic.

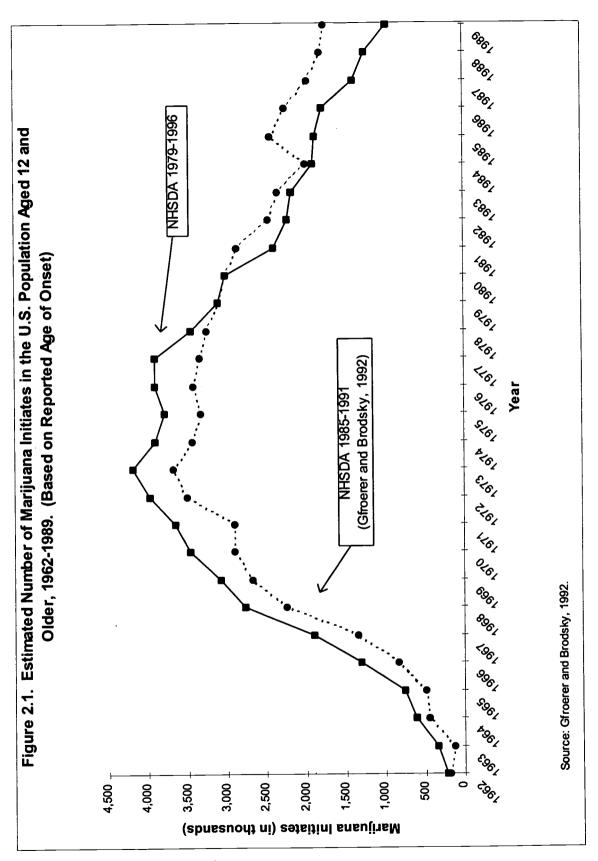

### 2.3 Identification Of Historical Incidence and Prevalence Periods

We examined changes in yearly rates of incidence and prevalence of marijuana use in the population to identify historical periods that marked the marijuana use epidemic and to delineate which birth cohorts experienced the epidemic in adolescence, according to the incidence and prevalence criteria. A problem in using these concepts to define the experiences of various birth cohorts is that incidence and prevalence rates do not show sharp changes, especially in the declining phase, so that the delineation of boundaries for the epidemic is somewhat imprecise. We examined data from the NHSDA and Monitoring the Future Study to identify these historical periods. As regards incidence, we extended the analyses conducted by Gfroerer and Brodsky (1992), Johnson and Gerstein (1998) and Johnson et al. (1996) in the NHSDA of the number of initiates by increasing the number of survey years both backward and forward in time and disaggregating the five-year grouped birth cohorts into single years. Because of differences in the age structure of the U.S. population over time, we also estimated incidence rates for onset for all ages, and by ages 16 and 19, by dividing the number of initiates by the size of the age-specific population at risk for initiation. [See Johnson and Gerstein (1998) for a discussion of the difficulties involved in specifying a denominator.] The incidence analysis generated approximate numbers because of imprecision in the denominator used to calculate the rates. The census-based population data for each year of historical interest, years 1962 to 1996, were only available for five-year age groups. In addition, we did not subtract from the base population sample the number of youths who had already started to use marijuana by each age up to age 19 and were no longer at risk for onset. We assumed that while this might bias somewhat the absolute rates it would not affect significantly the shape of the curve over the thirty-year interval. This assumption may be incorrect, however. We used as a denominator the number of persons aged 10-19 in each of the survey years. While the boundaries are somewhat imprecise, they are probably valid within a couple of years.

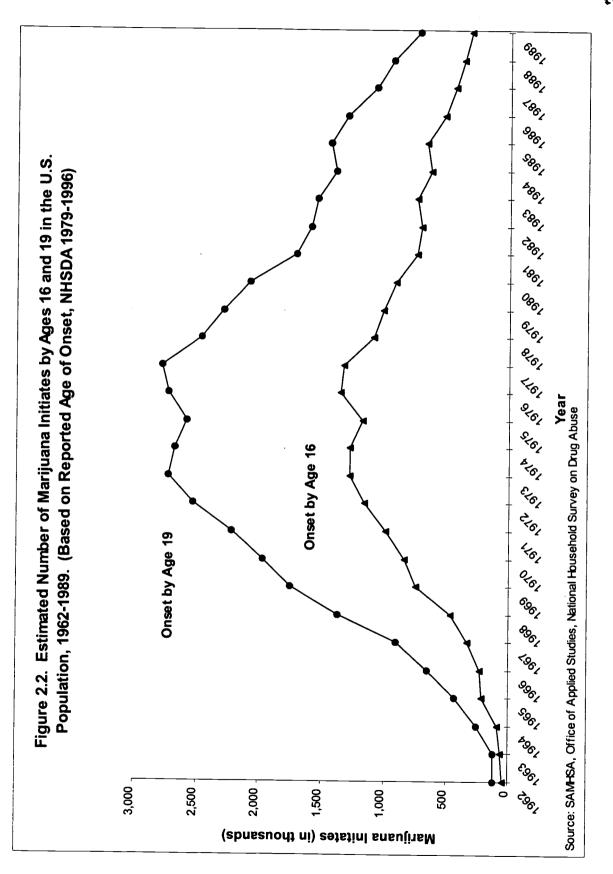

As regards prevalence, in addition to specific distributions of last year marijuana use in published NHSDA reports for 14 surveys (years 1974, 1976, 1977, 1979, 1982, 1985, 1988 and 1990-1996), we also examined last year use reported by high school seniors in *Monitoring the Future* for years 1976-1997 (Johnston et al., 1998; U Michigan, 1998).

Figure 2.1 shows the estimated number of marijuana use initiates in the total population from Gfroerer and Brodsky (1992) based on NHSDA 1985-1991 and a replication based on NHSDA 1979-1996. The number of marijuana use initiates in the total population increased from 1962 to 1972, peaked in the years 1973 to 1977, and beginning in 1978 declined gradually through 1989. The peak years were the same for individuals who started using marijuana by age 16 and those who started later by age 19 (Figure 2.2).

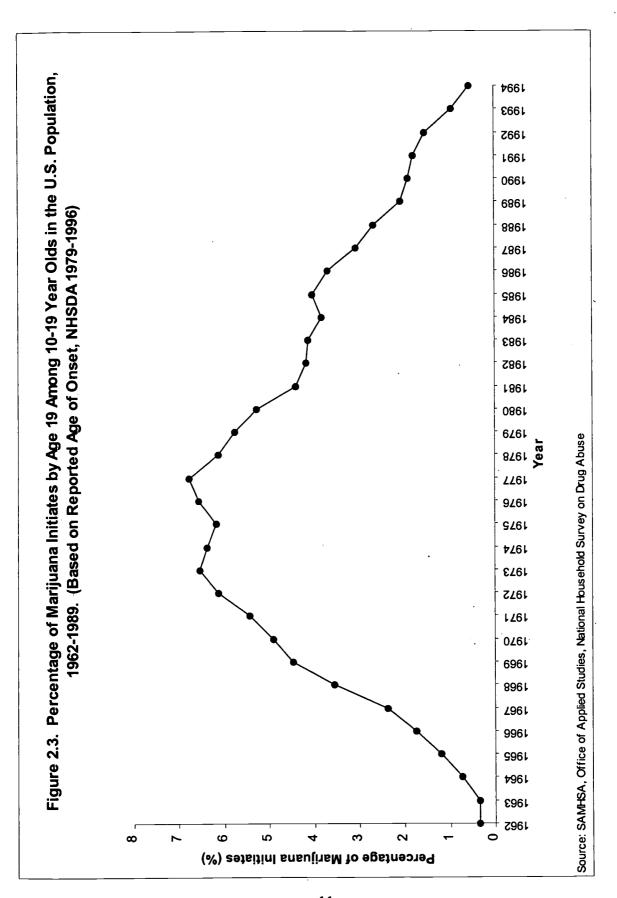

The same trend curve is observed for *percentages* of marijuana initiates (Figure 2.3) as was observed for *number* of initiates.

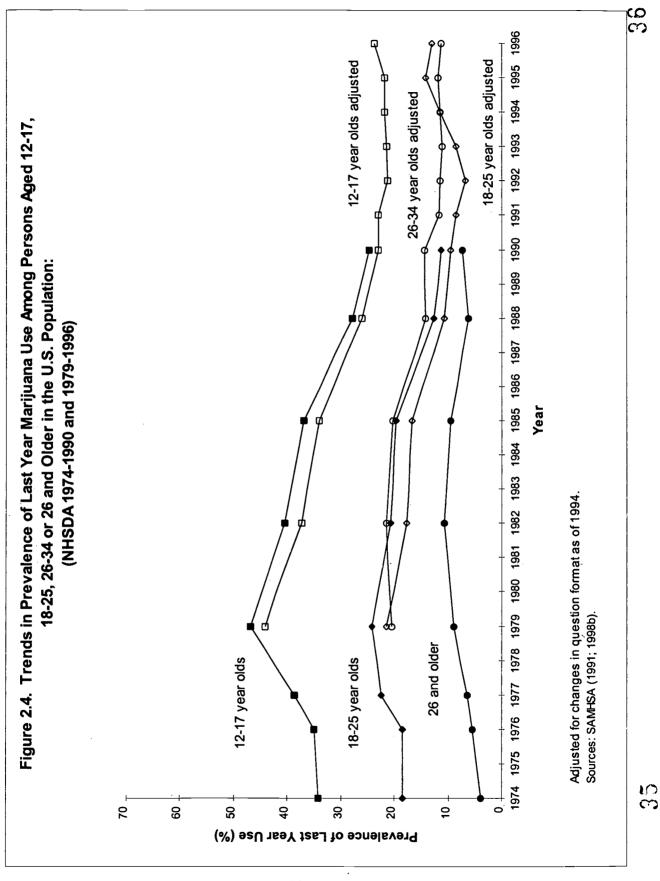

Since the NHSDA surveys were not administered annually until 1990, year-specific prevalence rates for prior years cannot be estimated (SAMSHA, 1998b). Table 2.1 displays trends in the prevalence of lifetime and last year use in the total population, while Figure 2.4 displays last year rates of marijuana use separately for age groups 12-17, 18-25 and 26 and older or 26-34, depending on the availability of published data for different survey years. The highest rates of last year use by those 26 years or older peaked in 1981-1984, while the rates for younger respondents peaked two years earlier in 1979. Similarly data from *Monitoring the Future* indicate that the rates of lifetime marijuana use by 12th graders peaked in 1979-1980 and rates of last year use in 1979 (Figure 2.5).

To highlight similarities and differences in incidence and prevalence patterns, Figure 2.6 displays on the same graph incidence rates, i.e., the estimated *percent* of initiates by age 19 from 1962 to 1994, as well as prevalence rates, i.e., the *percent* of last year marijuana use among 18 to 25 year olds from 1974 to 1996 in the NHSDA. While incidence rates by age 19 peaked in 1977, the highest marijuana prevalence in the NHSDA occurred in 1979 for adolescents and young adults.

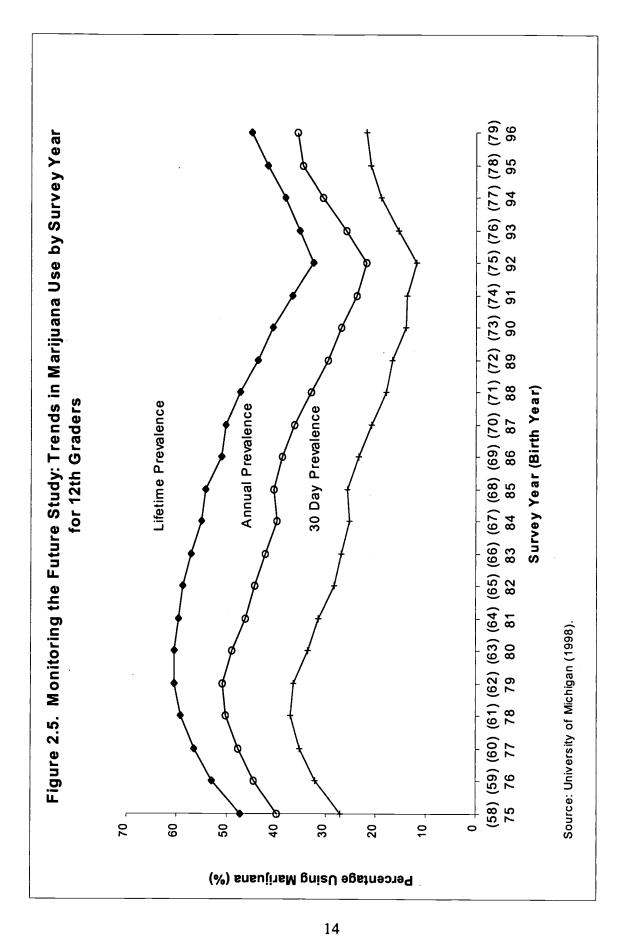

Based on changes in rates of incidence and last year prevalence identified from these analyses and from published findings, described above, we delineated five historical periods that defined different periods of the marijuana epidemic and characterized the cultural context with respect to marijuana use of the parents in their adolescence.

- (1.) 1963 and earlier: Pre epidemic; low incidence and prevalence of marijuana use.
- (2.) 1964-1971: Low marijuana incidence; the number of new users began to increase.
- (3.) 1972-1977: High marijuana incidence; the number of new marijuana users peaked and remained high among all age groups.
- (4.) 1978-1982: High marijuana use prevalence; the number of new users gradually decreased but the rates of prevalence were at their highest levels, especially among young adults 18-25 years old.
- (5.) 1983 and later: Post-epidemics; incidence and prevalence rates declined.

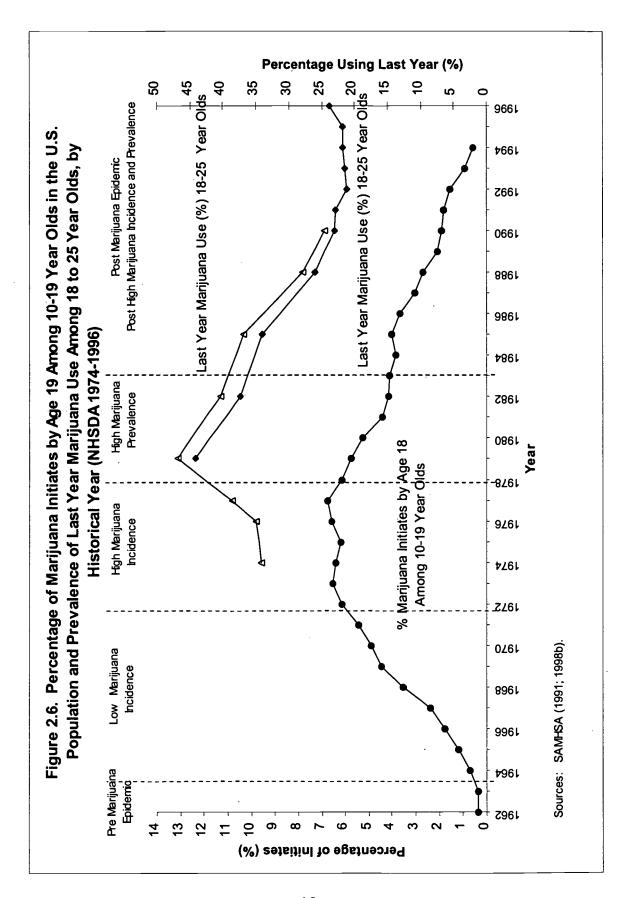

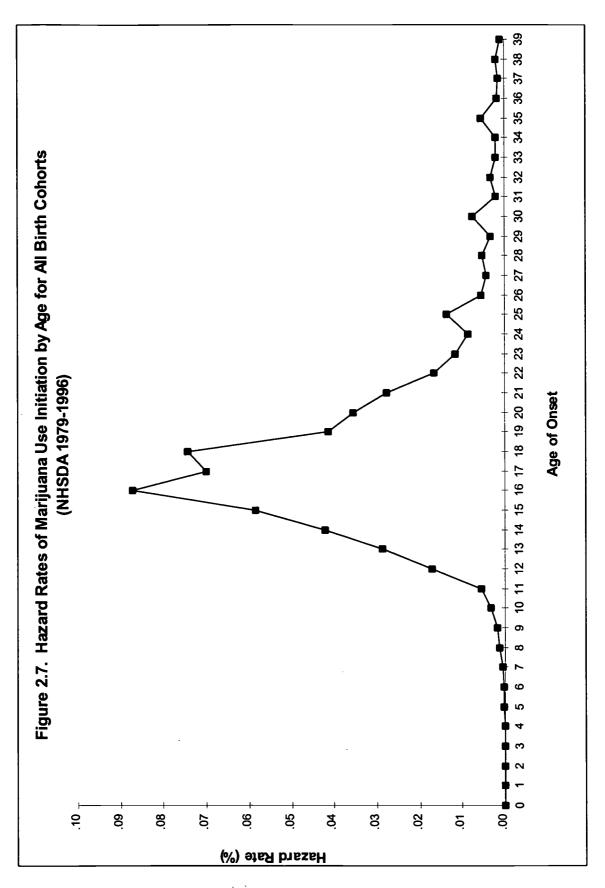

### 2.4 Identification of Ages at Risk for Initiation of Marijuana Use:

To place the relevant adolescent experience of different birth cohorts in the context of the five historical phases of the marijuana epidemic, it was necessary to define the developmental periods of greatest risk for initiation to marijuana use. Although the average age of marijuana onset decreased slightly over time from 1964 to 1989 (Gfroerer and Brodsky, 1992), for simplicity all cohorts were considered together.

To delineate the ages at highest risk for initiation of marijuana use, we examined the distribution of ages of onset among the self-reported users in the 1979-1996 NHSDA surveys (Table 2.2). We also calculated the hazard rate of marijuana use initiation (Figure 2.7). Since the hazard rates take right censoring (i.e., initiation may occur at a later age for many young respondents in the NHSDA) into account, they provide more precise estimates of the age-related risk for marijuana onset. Both the age-specific distribution of initiates and the hazards converged in highlighting ages 15-18 as the years of highest risk. Kandel and Logan (1984) had earlier shown by following a cohort over time that the hazard for onset of marijuana use starts to increase at age 13 and peaks at age 18. We concluded that ages 15-18 constituted the adolescent years of highest risk for marijuana initiation. These ages were used to characterize the duration of exposure to historical periods of marijuana use (or marijuana epidemic) for each cohort.

Appendix Figure A.2.1 illustrates the slight increases in the steepness of the hazard curves and shifting to the left among cohorts born between 1940 and 1984. This confirms Gfroerer and Brodsky's (1992) conclusion noted above that the average age of marijuana use onset decreased slightly from 1964 to 1989.

## 2.5 Cohort-Specific Exposure to Different Periods of the Epidemic

In a next step, we identified the parental birth cohorts who experienced different periods of the marijuana epidemic during ages 15-18. Some birth cohorts spent the years 15-18 entirely in one historical period ("pure" exposure); other birth cohorts spent the years 15-18 in two adjacent periods ("mixed" exposure) (Table 2.3).

Nine types of cohorts were identified as listed on Table 2.4.

The delineation of these nine groups of cohorts provided the basis for examining the impact of parental membership in the baby boom generation on child marijuana use. Since very few parents fell into the two post epidemic cohorts, these two groups were aggregated in the analysis.

# **CHAPTER 3: NHSDA METHODOLOGY**

## 3.1 Sample Design

The NHSDA is a survey of drug use in the general population that was conducted every two or three years from 1971 to 1988, and has been conducted annually as of 1990. The target population is the civilian, non-institutionalized population of the United States 12 years of age and older. Persons with no fixed address, residents of institutional quarters (such as jails and hospitals) and active military personnel are excluded. Oversamples have been consistently implemented for individuals in the ages of highest risk for drug use (ages 12-34), African-Americans and Hispanics since 1985, and six metropolitan statistical areas in 1991-1993. Current tobacco users were oversampled in the 1993-1995 surveys.

All descriptive analyses, including prevalence rates, cross-tabulations and univariate and multivariate logistic regression analyses were estimated by SUDAAN (Shah et al., 1992), which uses a Taylor series linearization technique to adjust for design effects. All analyses were based on weighted data. The significance of the differences between odds ratios was evaluated through the Wald test.

## 3.2 Sampling of Dyads

In a number of households, two respondents were selected for participation in each survey conducted since 1974. Before 1991, one of these respondents had to be a youth 12 to 17; in more recent surveys the age restriction was eliminated. This report is based on data beginning with the 1979 survey, since dyadic data from prior surveys are not available. In 1985 only one respondent was interviewed in each househould. Some information on the sampling of dyads is provided in the NHSDA public release codebooks (SAMHSA, 1992; 1994; 1995; 1996a; 1996b; 1997) and in the 1991-1996 sampling reports prepared by Research Triangle Institute (Allred et al., 1997; Jones et al., 1992; 1993; Jones and Folsom, 1993; 1994; 1995; 1996; Research Triangle Institute, 1997).

Through the 1996 survey, no consistent sampling design was applied to the selection of multiple respondents within households. The dyads were not a representative sample of parent-child pairs living in households in the U.S. and their selection was affected by the within-dwelling unit sampling procedures. These took into account the ethnic classification of the household head, the age group composition of the household and, in the 1993-1995 surveys, the cigarette smoking within the last month of 18-34 year old residents.

<sup>&</sup>lt;sup>1</sup> In the surveys prior to 1991, the target population was restricted to the household population of the contiguous 48 states. It included military personnel living in civilian housing but excluded all persons, military and civilian, living in civilian housing on military bases.

Prior to 1993, the population was divided into four age groups: 12-17, 18-25, 26-34 and 35+ years old. In 1992, the 35+ age group was partitioned into those 35-49 and 50+ years old. From 1993 to 1995, those aged 18-25 and 26-34 were classified as 18-34 smokers and nonsmokers, and sampled accordingly. The selection probabilities of particular age groups were based on the desired sample sizes for each age group by race/ethnicity. If an age group was selected for a particular dwelling and the dwelling contained more than one person in that age category, the interviewer would consult a table to determine the specific person to be interviewed. The probabilities of selecting a person within an age group were based on the sample size desired for the age group by race/ethnicity and the number of households expected to contain this age group by race/ethnicity. No more than two persons in one age group could be interviewed in a household. Before 1991, one of the two respondents had to be a youth aged 12-17. In more recent surveys, the age restriction was removed. In 1993-1996, one 12-17 year old and one adult were selected in the majority of cases. When two adult selections were made, most included one smoker and one nonsmoker in 1993-1995, and one 18-25 year old and one 26-34 year old in 1996.

## 3.3 NHSDA Parent-Child Dyads: Dyad Identification and Overview

Although NHSDA surveys were initiated in 1971, dyadic data were first collected in 1974 but data from the 1974, 1976 and 1977 surveys are not available for analysis. As noted above, parent-child dyads were not ascertained in 1985.

Two methods were used to identify parent-child dyads in the data sets. (1) For survey years 1979, 1982, 1988, 1990, 1991 and 1992, dyads were identified using two relational variables provided to us by Research Triangle Institute. One variable, Relationship of the DU Pair (DURELAT), identified the type of dwelling unit-pair (dyad). Four types were coded: parentchild, husband-wife, other/other, and not in a unit pair. After the parent-child dyads were identified, a second variable, Parent-Child Code (P-C), differentiated parent from child and was used to create the parent-child dyad file. (2) For survey years 1993, 1994, 1995 and 1996, parents and children were linked by us using information from the public use data files. Two individuals were classified as a parent-child pair if they lived in the same household and identified themselves as being a parent or a child of the other respondent. For all survey years (1979-1996), we imposed the criterion that the presumed parent was at least 12 years older than the child. In the 1991-1996 surveys, parent-child pairs with a child aged 12-25 were selected for analysis. We excluded those where the child was 26 years or older, since this represented an atypical living arrangement for this older age group. According to census data, from 1980 to 1996, only 10.4% to 12.3% of young adults aged 25-34 lived at home, and 52.6% to 54.4% of those aged 18-24 did so (U.S. Census Bureau, 1999). From 1989 to 1996, 94.9% to 96.4% of those aged 12 to 17 lived at home (U.S. Census Bureau, 1990-1991; 1992a, b; 1994; 1996a, b;

1998c)<sup>2</sup>. On average 97.0% of 12-17 year olds lived with their mothers; 77.0% lived with their fathers (U.S. Census Bureau, 1998a; b). Excluded dyads with a child 26 years old and older represented 2.4% of all the identified parent-child dyads in the surveys. Since parental self-identification of biological status in relation to the child was only ascertained beginning in 1994, and biological status could not be determined in prior years, both biological and non-biological parent-child pairs were included in the 1994 to 1996 surveys. In these three years, biological offspring accounted for 97.2% of the children in the dyads.

The analyses in this report are based on all ten available waves of parent-child data (1979, 1982, 1988, 1990-1996), including those conducted prior to 1991 where children were interviewed as part of a dyad unit pair only if they were aged 12-17. The 1994 survey included two components, 1994A and 1994B (see Section 3.5). A total of 9,463 parent-child dyads were identified in the aggregated 1979, 1982, 1988 and 1990-1996 surveys. Of the children, 88.6% were 12 to 17 years old, 11.4% were 18 to 25 years old. Close to 21% of all 12-14 year old NHSDA respondents were included in a parent-child dyad, 15.6% of all 15-17 year olds, and 3.1% of all 18-25 year olds (Table A.3.1). The aggregate and year-specific sample sizes of parent-child dyads with children aged 12-25 are reported in Table 3.1 by sex of parent and child. The number of parent-child pairs is much larger in recent than in earlier waves, reflecting increases in the total sample size of the surveys.

## 3.4 Dyad Level Weights

All dyad level weights were constructed and provided by Research Triangle Institute. The year-specific dyad level weights were derived from the person-level sampling weights. Each dyad level weight was the sum of the parent and child year-specific person-level sampling weights, divided by the total number of individuals in the household aged 12 and older. This constructed weight was applied to both members of each dyad.

For the 1979, 1982, 1988, 1990-1996 aggregate sample, new dyad level weights were constructed by multiplying the year-specific dyad weight for each case by the year-specific total number of dyads, and dividing by a constant<sup>3</sup>. The constant was the sum of the year-specific weights weighted by the number of cases per year, divided by the total cases in the aggregate sample (Personal communications, Michael Witt, 1/30/98, 5/26/98)

<sup>&</sup>lt;sup>2</sup> Data for 1980 to 1988 are available for 10-17 year olds as a group. The range is 96.0% to 96.8% (U.S. Census Bureau, 1981; 1982; 1985; 1986; 1987; 1988; 1989).

<sup>&</sup>lt;sup>3</sup> For selected analyses, aggregate samples consisting of the 1991-1994A and 1994B-1996 surveys were used. Dyad level weights were also constructed for these aggregate samples.

#### 3.5 Changes in Interview Format in 1994

The NHSDA schedule is a structured one-hour personal interview, in which the drug questions are answered by respondents in self-administered modules. Until 1994, questions pertaining to tobacco use were answered orally to the interviewer.

In 1994, the interview schedule was substantially revised and selected data processing procedures were modified as well. Two versions of the interview schedule (Forms A and B) were administered in a split sample design to assess the consequences of the changes. Form A retained all the core questions from prior surveys and was administered to one-fifth of the respondents.

Form B constituted the revised version and was administered to four-fifths of the sample. The revisions included changes in the wording of selected drug-related questions; the presentation of the tobacco module in a self-administered format rather than being administered by the interviewer as in prior surveys; the addition of questions on mental health and access to mental health care. [See SAMHSA (1996c) for a detailed presentation of the major changes in the interview schedule]. In addition, different imputation procedures were implemented with data from Form B to define an individual as a drug user in the presence of missing data on drug use reports. In particular, while respondents who answered positively to any question dealing with use in the last twelve months were classified as marijuana users through 1994A, as of 1994B, only answers to the recency of use question were used.

The prevalence estimates of substance use differ between Forms A and B. Estimates of illicit drug use are higher in Form A than Form B, whereas estimates of licit drug use are higher in Form B than Form A, especially for last month tobacco use reported by adolescents. The rates of lifetime and last year marijuana use among age groups are slightly higher in Form A than Form B, with selected exceptions for adults aged 26 and older. For example, the rates of lifetime marijuana use are 16.0% in Form A compared with 13.6% in Form B among respondents aged 12-17; 43.4% compared with 41.9% among those aged 18-25; 56.9% compared with 52.7% among those aged 26-34; and 28.4% compared with 25.4% among respondents aged 35 and older (Table A.3.2). A similar pattern was observed in self-reported marijuana use in the last year. Given these differences in self-reported use, survey year specific analyses for 1994 were conducted for Forms A and B separately.

# 3.6 Advantages and Disadvantages of the NHSDA

The NHSDA has both advantages and disadvantages for the study of parent-child association in marijuana use.

The advantages include: (1) the large number of parent-child dyads, in which independent data on drug behavior were obtained from each person; (2) the inclusion of mothers and fathers, albeit only one parent per family; (3) the availability of detailed drug use information on both

members of the dyads; (4) the overrepresentation of minorities; and (5) the multiple waves of data available since the late 1970's. The NHSDA surveys include families in which parents were members of the baby boom generation (i.e., the 1946-1964 birth cohorts), families in which the parents were born before 1946, and a very small number who were born after 1964.

The NHSDA also has limitations: (1) The dyads are not a representative sample of parent-child pairs living in households in the United States. Reflecting the gender distributions of parents who participated in the NHSDA as a whole, there is an under-representation of fatherchild dyads compared with the distribution of fathers residing in households in the U.S. population (see Chapter 4, Section 4.2). Rates of marijuana use are lower among parents and children interviewed as members of dyads than as household members (see Chapter 5, Section 5.1.c). (2) The sampling selection procedures for the overall sample and for multiple respondents in a household varied across survey years, so that the resulting dyadic samples are not necessarily similar over time. (3) The data set includes very little information about factors other than drug use, especially individual characteristics of young people, which are important predictors of drug use. As a result, few variables could be used as controls to provide more accurate estimates of the influence of parental drug consumption on offspring use or as predictors of child marijuana use. (4) Finally, the data are cross-sectional. While we interpret the observed association between parent and child as reflecting the influence of the parent on the child, it is possible, although not likely, that the association reflects in part the influence of the child on the parent.

These limitations notwithstanding, the NHSDA provides an unusual opportunity to address important questions related to the extent of parental influence on children's marijuana use in different parental birth cohorts.

#### 3.7 Measurement of Variables

The definitions of variables was complicated by the fact that the format of the questions, and the coding and imputation of the variables underlying the constructed variables changed over the course of the 10 surveys included in the analysis. Most of the changes took place in the 1988 and 1994B surveys.

The variable labels specified below are from the public use codebooks. Variable labels denoted with an "X" are those that we constructed from available public use variables. Unless otherwise indicated, variables were available in all the surveys included in this report. All imputed variables were constructed by SAMSHA. Details about the construction of the drug use variables and other selected variables appear in the Technical Appendix: Construction of Drug Use and Other Variables.

The differential availability of variables across the surveys determined the selection and grouping of different surveys for analyses based on these variables.

#### 3.7.a Marijuana Use Variables

Two dimensions of the child's marijuana use were examined to assess variations in patterns of parental influence on the child lifetime marijuana experimentation and current use: (1) ever used marijuana; and (2) used in the past year. Six marijuana variables were examined for parents: (1) ever used marijuana; (2) used in the past year; (3) a combination of use lifetime and past year to identify former users; (4) frequency of use in the lifetime; (5) frequency of use in the past year; and (6) frequency of use in the past 30 days.

Parent and child lifetime marijuana use (MRJFLAG): 0=never used marijuana; 1=ever used.

Parent and child past year marijuana use (MRJYR and MRJYRX). For parents and children, a binary variable (MRJYR) was created: 0=no marijuana use in the past year; 1=used in the past year. For parents, a trichotomous variable (MRJYRX) was also created: 0=never used marijuana; 1=former use, not in the past year; 2=used in the past year.

Parent frequency of lifetime marijuana use (MJTOTX): 0=never used marijuana; 1=used 1-10 times/days lifetime; 2=used 11-99 times/days lifetime; 3=used 100 or more times lifetime.

Parent number of days used marijuana in the past 12 months (MJYRFRQX): 0=never used marijuana; 1=former use, not in the past 12 months; 2=used 1-200 days in the past 12 months; 3=used 201-300 days in the past 12 months. Available in 1988 and 1990-1996. Text refers to the variable as "in the past year."

Parent number of days used marijuana in the past 30 days (MJDAY3OX): 0=never used marijuana; 1=former use, not in the past 30 days; 2=used 1-10 days in the past 30 days; 3=used 11-30 days in the past 30 days. Text refers to the variable as "in the past month."

# 3.7.b Other Drug Use Variables: Cigarettes, Alcohol, Cocaine

Parent lifetime cigarette use (CIGFLAG): 0=never used cigarettes; 1=ever used.

Parent past year cigarette use (CIGYRX): 0=never used cigarettes; 1=former use, not in the past year; 2=used in the past year.

Parent smoked 100 or more cigarettes in lifetime (CIG5PKX): 0=never used cigarettes or did not use 100 or more cigarettes in lifetime; 1=used 100 or more cigarettes in lifetime.

Parent number of cigarettes per day in the past 30 days (CIGMFRQX): 0=never used cigarettes; 1=former use, not in the past 30 days; 2=1-15 cigarettes per day in the past 30 days; 3=16-35 cigarettes per day in the past 30 days; 4=36 or more cigarettes per day in the past 30 days. Text refers to the variable as "in past month."

Parent number of cigarettes smoked daily (PACKSX): 0=never used cigarettes; 1=smoked 1-5 cigarettes per day; 2=smoked 6-15 cigarettes per day; 3=smoked 16-25 cigarettes per day; 4=smoked 26-35 cigarettes per day; 5=smoked 36 or more cigarettes per day.

Parent lifetime alcohol use (ALCFLAG): 0=never used alcohol; 1=ever used.

Parent past year alcohol use (ALCYRX): 0=never used alcohol; 1=former use, not in the past year; 2=used in the past year.

Parent frequency of past year alcohol use (IRALCFQX). Eight categories. See Technical Appendix, Section A.1.b.

Parent number of times very drunk or high in the past 12 months (DRUNKYRX). Ten categories. See Technical Appendix, Section A.1.b.

Parent quantity/frequency of alcohol use in the past 30 days (ALCMFRQX): 0=never used alcohol; 1=former use, not in the past 30 days; 2=used less than 2 drinks per day in the past 30 days; 3=used 2 or more drinks per day in the past 30 days. Available in 1988 and 1990-1996.

Parent lifetime cocaine use (COCFLAG): 0=never used cocaine; 1=ever used.

Parent past year cocaine use (COCYRX): 0=never used cocaine; 1=former use, not in the past year; 2=used in the past year.

Parent frequency of lifetime cocaine use (COCTOTX1 and COCTOTX2). Two versions were constructed. A four category version (COCTOTX1): 0=never used cocaine; 1=used 1-10 times/days lifetime; 2=used 11-99 times/days lifetime; 3=used 100 or more times/days lifetime. An eight category version is described in the Technical Appendix, Section A.1.b.

Parent frequency of past year cocaine use (IRCOCFQX). Nine categories. See Technical Appendix, Section A.1.b.

#### 3.7.c Sociodemographic Variables

Ten sociodemographic variables were examined. See Technical Appendix, Section A.2.a. for further detail.

Parent and child age (IRAGE). Imputed variable, coded in years. Children were classified into three age groups: 12-14, 15-17 and 18-25 years old. Parents were classified according to their children's ages. Age ranges of parents for each of the three children's age categories were 24-73 years; 27-80 years; and 31-74 years, respectively.

Parent and child sex (IRSEX). Imputed variable: 1=male; 2=female.

Parent race/ethnicity (IRACE). Imputed variable, four categories: 1=white; 2=African-American; 3=Hispanic; 4=other. Across surveys, ethnicity was based on self-reports for 95.0% of individuals and on interviewers' observations in the remaining cases. To simplify the analysis of dyadic similarity, a single variable based on parental ethnicity was used to characterize the ethnicity of parent and child. In 97.1% of dyads, both respondents were in the same category.

Parent and child birth cohort (PCOHRTX) and CCOHRTX). Constructed variable. Nine groups of parental birth cohorts (PCOHRTX) were identified based on exposure to historical periods of the marijuana epidemic during ages 15-18, as described in Chapter 2: 1=born 1945 and earlier; 2=born 1946-1948; 3=born 1949-1953; 4=born 1954-1956; 5=born 1957-1959; 6=born 1960-1962; 7=born 1963-1964; 8=born 1965 and 1967; 9=born 1968 and after.

Children were classified into five groups of birth cohorts, each aggregating five birth years. (CCOHRTX). Constructed variable, five categories: 1=born before 1964; 2=born 1965-1969; 3=born 1970-1974; 4=born 1975-1979; 5=born 1980-1984.

Parent and child marital status (IRMARIT). Imputed variable, five categories: 1=married; 2=divorced/separated; 3=widowed; 4=never married; 5=legitimate skip for respondents aged 12-17 in 1979 and 1982, and aged 12-14 in 1988, 1990-1996.

Parent and child education (EDUCCT2X). Recoded variable, five categories: 1=less than high school/drop out; 2=high school graduate; 3=some college; 4=college graduate; 5=in secondary school.

Child school dropout (CDRPOUTX). Constructed variable. Based on variable EDUCCT2X: 0=not a dropout; 1=dropout.

Household income (FAMINC). Five categories of total family income: 1=\$0-\$8,999; 2=\$9,000-\$19,999; 3=\$20,000-\$39,999; 4=\$40,000-\$74,999;  $5=\$75,000^+$ . Available in 1990-1996.

Region of the country (REGION). Four categories: 1=Northeast; 2=North Central; 3=South; 4=West.

Population density (PDEN). Three categories based on the 1990 Census: 1=segment in an MSA with 1 million or more persons; 2=segment in an MSA with fewer than 1 million persons; 3=segment not in an MSA. Available in 1990-1996.

#### 3.7.d Personal Characteristic Variables

See Technical Appendix, Section A.2.b, for further detail.

Parent depression in past 12 months (MDE1): 0=probable non-case; 1=probable case.

Parent anxiety in past 12 months (GAD1): 0=probable non-case; 1=probable case.

Parent and child delinquency in past 12 months (DELQX). Scores ranged from 0-12. Additive index based on 12 delinquency items. Available in 1991-1994A and 1995.

Child behavioral problem in past six months (PR\_BEHAV). Administered only to 12-17 year olds in 1994B-1996: 0=no behavioral problem; 1=behavioral problem. Recoded binary variable derived from 100 items from the Achenbach Youth Checklist (YSR). The Behavioral Problem Scale was the summation of the Delinquent and Aggressive Behavior Syndrome raw scores. For boys a score of 19 and for girls a score of 17 indicated a behavioral problem.

Child emotional problem in past six months (PR\_EMOT). Administered only to 12-17 year olds in 1994B-1996: 0=no emotional problem; 1=emotional problem. Recoded binary variable derived from 100 items from the Achenbach Youth Checklist. The Emotional Problem Scale was the summation of the Withdrawn, Anxious/Depressed and Somatic Complaints Syndrome raw scores (minus overlap for the unhappy/sad/depressed item). For boys a score of 17 and for girls a score of 22 indicated an emotional problem.

Parent and child perceived risk of occasional and regular marijuana use (RSKMJOCX and RSKMJRGX). Recoded variables, three categories: 1=great risk; 2=moderate risk; 3=slight/no risk. Two questions: "How much do you think people risk harming themselves physically and in other ways when (1) they smoke marijuana occasionally (RSKMJOCC); and (2) smoke marijuana regularly (RSKMJREG)?" The original four categories included: 1=no risk; 2=slight risk; 3=moderate risk; 4=great risk. Categories 3 and 4 were combined. Three-category reverse coded versions were created. Available in 1988, 1991-1994 (A and B) and 1995.

Table 3.1. Number of Parent-Child Dyads with Children Aged 12-25<sup>1,2</sup> by Gender of Parent and Child by Survey Year (NHSDA 1979, 1982, 1988, 1990, 1991, 1992, 1993, 1994A, 1994B, 1995, 1996)

# CHAPTER 4: SOCIODEMOGRAPHIC CHARACTERISTICS OF PARENT-CHILD DYADS

Nine demographic characteristics of parents and children were examined: age, sex, ethnicity, education, including child school drop out status, marital status, household income, region of the country and population density. Most findings discussed below are for the aggregated 1979-1996 dyads. In addition, characteristics of respondents included in dyads and of those interviewed as single respondents within a household are presented.

#### 4.1 Age

The average age of the children was 15.1 years (sd= 2.6). The majority (88.6%) were 12 to 17 years old: 47.3% were 12-14 years old, 41.3% were 15-17 years old, and 11.4% were 18-25 years old (Table 4.1). The detailed distribution of children's ages is presented in Appendix Table A.4.1. Except for survey years prior to 1991, the age distributions were fairly consistent across the waves of dyadic data (Table 4.1 and Appendix Table A.4.1). From 1991 through 1996, children aged 12-17 years old comprised between 81.8% and 94.2% of the child samples. Parents were on average 41.5 years old (sd= 7.2, range 24-80 years), with fathers about 3 years older than mothers ( $\bar{x}\bar{x}=43.1$ , sd= 8.6 and  $\bar{x}\bar{x}=40.4$ , sd= 6.2, respectively, p<.001) (Table 4.2). The average ages of parents increased from 39.0 years (sd= 6.2, range= 24-73 years), when their children were 12-14 years old, to 42.9 years (sd= 7.0, range= 27-80 years), when their children were aged 15-17 years old, and to 47.1 years (sd= 7.5, range= 31-74 years), when their children were 18-25 years old.

The average difference in age between parents and children was 26.4 (sd= 6.5) years.

#### 4.2 Sex

The children were evenly distributed between boys and girls. By contrast, there were fewer father-child (40.4%) than mother-child pairs (59.6%), with 22.1% father-son, 18.3% father-daughter, 28.8% mother-son and 30.7% mother-daughter pairs in the aggregated surveys (Table 3.1). There were slightly more same-sex (52.8%) than cross-sex (47.2%) pairs. The distribution of males and females across the year-specific samples was fairly consistent for both children and parents (Table 4.1 and 4.2). Father-child pairs are underrepresented in the NHSDA. In the U.S. in 1990 and 1993, the ratios of the number of adolescents 12-17 years old living in households with a father over those living with a mother were .82 and .81, respectively (U.S. Census Bureau, 1989-1990; 1993) compared with a ratio of .45 for father-child over mother-child dyads in the 1979-1996 NHSDA. The uneven representation of mothers and fathers in the NHSDA sample reflects the lower participation of males than females in household surveys, including the NHSDA (Section 4.7), and probably introduces an unknown bias in the parental sample.

#### 4.3 Ethnicity

In the total aggregate sample, the ethnic composition was 63.4% white, 20.5% African-American, 14.0% Hispanic and 2.1% other (Table 4.2). However, the ethnic distribution fluctuated from year to year, sometimes dramatically. In 1988 and 1990, the proportions white were extremely low (3.9% and 10.8%, respectively); in 1993 there were many more whites (72.1%) than in 1991 (53.9%) and in 1996 (50.7%).

This year-to-year fluctuation introduces some additional unspecified bias in the sample.

#### 4.4 Education

The majority of the youth sample consisted of 12-17 year old adolescents enrolled in secondary school (84.6%); 5.9% had a high school degree, 5.3% had dropped out of high school, 3.5% had attended some college and .6% had a college degree (Table 4.1). Among the parents, 23.7% did not have a high school degree, 35.7% had a high school degree, 21.6% had attended college, and 19.1% had a college degree or higher education (Table 4.2).

#### 4.5 Marital Status

Seventy-eight percent of the parents were married; 14.0% were divorced or separated (Table 4.2). Almost all (99.1%) the children were unmarried (Table 4.1).

#### 4.6 Household Income

In the aggregate 1990-1996 sample, the annual household income was less than \$9,000 in 8.1% of cases, \$9,000-\$19,999 in 17.4%, \$20,000-\$39,999 in 32.3%, \$40,000-\$74,999 in 31.4%, and more than \$75,000 in 10.8% of cases (Table 4.2).

#### 4.7 Dyad and Non-Dyad Respondents Compared

To assess the impact of non-systematic sampling of multiple household respondents, we compared the sociodemographic characteristics of individuals interviewed as parts of dyads and those interviewed as singletons. The comparison group of non-dyadic adults was restricted to parents. An exact match according to adolescent ages could not be implemented in two early surveys (1979 and 1982) because parents were only asked about 12-17 year old children as a group. Given the small representation of young adults 18-25 in the child sample, the comparison of dyads and non-dyads was done separately for respondents 12-17 and 18-25 years old.

Dyadic and non-dyadic respondents differed on every characteristic, except child sex

<sup>&</sup>lt;sup>4</sup> Due to the small number of cases in the "other" ethnic group, it is not considered in the ethnic-specific analyses.

(Table 4.3). The differences were relatively small but highly significant because of the large sample sizes. In particular there were more African-Americans and fewer whites in dyads than in non-dyads (p<.001). Among the children, a lower percentage was married among dyads than non-dyads, especially among those 18 to 25 years old. A lower percentage of adolescents had dropped out of school whereas a lower percentage of 18 to 25 year olds were college graduates in the dyads than the non-dayds (Table 4.4).

Parents and children in dyads are not a representative subsample of parents and children interviewed in the NHSDA.

# CHAPTER 5: PREVALENCE AND ASSOCIATION OF MARIJUANA USE AMONG CHILDREN AND PARENTS

## 5.1 Prevalence of Marijuana Use Among Children and Parents

Prevalence rates of marijuana use among parents and children in the total dyads and by sociodemographic characteristics are presented as background to the analysis of association in patterns of use within dyads. Data for 12-17 year olds are available in all surveys but only in 1991-1996 for 18-25 year olds. To adjust for the variable age distributions of children in dyads from different surveys, age standardized estimates were calculated separately among 12-17 year olds for 1979-1996 and among 18-25 year olds for 1991-1996 based on the 1991 distribution of child age. Data for the aggregated 1979-1996 surveys are presented in Tables 5.1 and 5.2 and for specific years in Appendix Tables A.5.1 and A.5.2. Use among children and their parents follow well described age, gender and ethnic related patterns.

## 5.1.a Child Patterns of Marijuana Use

In the 1979-1996 aggregate sample, 15.1% of children aged 12-17 had ever used marijuana and 11.9% had used it in the last year (Table 5.1). In 1991-1996, 10.8% and 8.4% of 12-17 year olds had done so; 40.1% of youths aged 18-25 had used marijuana in their lifetime and 23.7% in the last year.

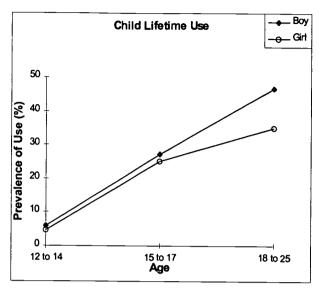

The increasing rates of use with increasing age followed well documented age related trends. Adolescents were differentiated into two age groups, 12-14 and 15-17 years old. In 1991-1996, there was a five-fold increase in rates of lifetime marijuana use among older adolescents aged 15-17 years (19.2%) compared with younger adolescents aged 12-14 years (3.2%), and a further doubling from ages 15-17 to ages 18-25 (40.1%).

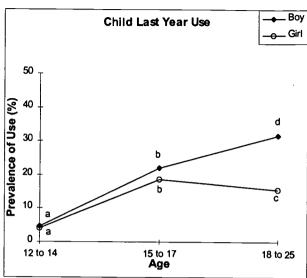

While in the total sample of 12-25 year olds, boys were more likely than girls to use marijuana lifetime and in the last year (p's<.001), this sex difference did not appear among adolescents aged 12-14 and 15-17 for lifetime and last year use (see Figure 5.1). The interaction term of child age and sex was statistically significant only for last year use (logistic regression, p<.05).

There were no statistically significant ethnic differences in rates of lifetime and last year marijuana use in the total sample of youths.

Figure 5.1. Prevalence of Lifetime and Last Year Marijuana Use Among Children Aged 12-25, by Child Age and Sex<sup>1,2</sup> (NHSDA 1979-1996)

For child last year marijuana use, percentages with different superscripts are significantly different from each other.

## 5.1.b Parental Patterns of Marijuana Use

In the aggregate 1979-1996 sample, 32.8% of parents had ever used marijuana in their lifetime but only 5.3% had used in the last year (Table 5.2). Despite the large number of dyads in the sample, this low prevalence rate resulted in a relatively small number of families (N= 572) in which the parents reported to be still using marijuana within the last year (343 mothers, 229 fathers). Parents who reported using marijuana within the last year preceding the interview reported greater lifetime usage than those who had stopped using marijuana. In the 1979-1994A aggregated surveys, 41.2% of current users reported having ever used marijuana 100+ times compared with 17.7% of former users (Appendix Table A.5.11). Lifetime parental rates increased from 1979 to 1994, peaked at 47.9% in 1994A (36.3% in 1994B), and declined in 1995 and 1996. Parent last year marijuana use remained stable during the 17-year period covered by the surveys (Appendix Table A.5.2). The increase in lifetime prevalence over most of the period covered by the surveys reflects historical changes in rates of marijuana use initiation experienced in their adolescence by parents from different birth cohorts.

<sup>&</sup>lt;sup>1</sup> Weighted estimates.

SUDAAN PROC LOGISTIC (Wald F-test) was used to test for age and sex differences in lifetime and last year marijuana use.

Fathers had higher rates of marijuana use than mothers: 38.9% of fathers and 28.7% of mothers reported having used marijuana in their lifetime; 7.1% of fathers and 4.1% of mothers reported using it in the last year (p's<.001) (Table 5.2). This pattern was very stable across individual survey years (Appendix Table A.5.2).

Parental lifetime marijuana use decreased with increasing child age as parental age increased.

There were significant ethnic differences in patterns of parental marijuana use. African-American and white parents had higher rates of lifetime marijuana use than Hispanic parents (p's<.001); African-American parents had higher rates of last year use than white and Hispanic parents (p's<.001) (Table 5.2). The different ethnic patterns observed among children and their parents mirror the epidemiological finding that, in adolescence and early adulthood, whites usually have higher rates of drug use than minorities, while the ethnic patterns reverse beginning in middle adulthood.

## 5.1.c Drug Use Among Respondents in Dyads and Those Not in Dyads

We noted earlier that the dyads in the NHSDA were not selected to constitute a representative sample of parent-child pairs in the United States, and that the sociodemographic characteristics of parents and children in dyads differed somewhat from those not in dyads. Two features of the epidemiology of marijuana use differed in the two groups as well, especially for dyads with the youngest adolescents 12-14 years old.

We compared the rates of self-reported marijuana use by children and parents in dyads with youths of similar ages and parents not included in dyads. The rates of lifetime and past year marijuana use among 12-14 year olds and of lifetime use among 18-25 year olds were generally significantly higher in the non-dyadic sample than in the dyadic sample of children (Table 5.3). Rates of use for parents not in dyads, controlling for child age, were generally the same in dyads and non-dyads. The only statistically significant difference was the higher lifetime rates of parents of 12-14 year olds not in dyads (Table 5.3). Detailed year-specific data are presented in Appendix Tables A.5.3 and A.5.4.

Rates of use over time in the sample of youths in dyads fluctuated more and rates for 18-25 year olds deviated somewhat from historical trends observed among youths in the United States during the same historical period. This can be seen from a comparison of trends in last year prevalence of use among youths aged 12-17 and 18-25 for the total NHSDA (Figure 1.1) and for the dyads (Appendix Figure A.5.1). Rates of marijuana use among 18 to 25 year olds in the dyads started to decline as of 1995 at a time when, in the U.S. as a whole, rates of use in that age group were still increasing.

#### 5.2 Association in Marijuana Use Between Parents and Children

The influence of parents on children was inferred from the extent of association in marijuana use between them. As noted earlier, although the data are cross-sectional, we use the term parental influence, since we assume that it is unlikely that parents use marijuana in response to their children's use.

The association between children's and parents' patterns of marijuana use within dyads was estimated by odds ratios between child and parent use. Cross-tabulations for the aggregated 1979-1996 surveys are presented in Table 5.4 and odds ratios in Table 5.5. Cross-tabulations for each of the 10 surveys separately are presented in Appendix Tables A.5.5-A.5.9 (A.5.5 by child age, A.5.6 by child sex, A.5.7 by parent sex, A.5.8 by dyad type, A.5.9 by ethnicity) and odds ratios in Appendix Table A.5.10.

#### 5.2.a Cross-Tabulations Between Parent and Child Marijuana Use

Parental lifetime and last year use. In a first step, the children's lifetime and last year marijuana use was examined as a function of parental history of marijuana use. There were consistently positive and significant associations between the marijuana behavior of parents and children (Table 5.4). In the total sample of youths aged 12-25, the proportion reporting to have ever used marijuana was more than forty percent higher when parents reported to have ever used marijuana in their lives (22.9%) compared with when parents had never used (15.6%). Rates of last year use by the children were sixty percent higher (17.5% and 11.0%, respectively, in each type of family). When parents reported using marijuana within the last year almost twice as many (21.9%) of the children had also used marijuana in the same period compared with when parents had not used marijuana (12.7%).

Parental lifetime and last year use were considered simultaneously in order to distinguish the influence of former from current use (i.e., use within the last year). In the total sample, the percentages of children using marijuana, whether lifetime or last year, were similar for former and current parental marijuana users and not statistically significantly different from each other (Table 5.4). When the sample was disaggregated by age, however, a difference appeared among the youngest adolescents aged 12-14. There were higher percentages of lifetime and past year users among the children of current than of former marijuana users (differences statistically significant at P<. 05).

#### 5.2.b Measures of Association Between Parent and Child Marijuana Use

The odds ratio, a measure of association that is insensitive to marginal distributions, provides a more appropriate assessment of parent-child association than the percentages of dyad members with similar patterns of use. In a first step, univariate regression models were estimated to predict the child lifetime and last year marijuana use as a function of parental pattern of marijuana use, without control for any other variable. Models were run with different definitions of parental marijuana use: lifetime, last year, combined lifetime-last year (Table 5.5).

The influence of lifetime and last year parental use was similar. The unadjusted odds of children using marijuana ever or within the last year when their parents were lifetime or last year users were almost identical (1.6-1.9). The odds varied slightly from year to year (Appendix Table A.5.10). The highest odds appeared in the very small 1994A sample and reflected imprecision of the estimates. The joint examination of lifetime and last year use confirmed the descriptive finding reported above regarding the relative impact of current versus former parental use on lifetime use by the child. In the total sample, the effects were not significantly different (Table 5.5). Although, compared with never users, last year parental users were more likely (OR=2.3, p<.001) than former users (OR=1.6, p<.001) to have a child who reported using marijuana in the last year, the difference between the odds was not statistically significant. As discussed above with respect to rates of use, the patterns changed somewhat by children's age and ethnicity. Among the youngest children and Hispanics, parental current use had a stronger effect than former use (differences in the odds ratios significant at p<.01).

Parental influence was apparent for children of all ages (Table 5.5). The odds in the age-specific groups were consistently higher than in the sample as a whole, reflecting the association of child age with levels of marijuana use. The association of parental lifetime use with child lifetime use was significantly higher for the oldest children than the two younger groups (p<.05; Wald test); the association of parental last year use with child lifetime use was significantly higher both for the oldest and youngest offspring than those 15-17 years old (p's<.05; Wald test). Parental influence displays a curvilinear pattern, declining throughout adolescence and increasing among young adults aged 18 to 25. This probably reflects the closeness and dependence on parents of these older youths who are still living at home, although some are married.

The association of children's marijuana use with mothers was stronger than with fathers, especially when the parent was still using marijuana within the last year preceding the interview (Table 5.5). However, the differences were not statistically significant.

Parental lifetime marijuana use had statistically significant and similar associations with boys' and girls' lifetime and last year use (Table 5.5). Parental use in the last year, however, was significantly associated with the lifetime and last year use of sons only (ORs=2.3,2.2 p's<.001), but the differences between boys and girls were not significant.

Trends appeared in same- and cross-sex patterns of association between parents and children, but they were not statistically significant (Table 5.5). When fathers smoked, the odds of smoking by children were elevated only among sons; when mothers smoked, the odds were elevated among sons and daughters. For example, when fathers used marijuana in the last year, sons were more than twice as likely to use marijuana both in their lifetime and in the last year (ORs=2.1 and 2.0, p's <.05) while daughters were not (OR=1.1). When mothers used marijuana in the last year, the odds ratios for sons' and daughters' last year use were 2.5 (p<.01) and 2.0 (p<.05), respectively. However, the three-way interactions between parent sex, child sex and parent marijuana use on child marijuana were not statistically significant (data not presented). Consequently, all multivariate analyses were implemented without differentiating parents and children by gender.

Across ethnic groups, parental lifetime marijuana use was positively and significantly associated with child lifetime and last year marijuana use (Table 5.5). Ethnic differences in patterns of association appeared only with respect to parental last year use. The association of parental last year marijuana use with child lifetime and last year marijuana use was higher among Hispanics (ORs=3.3, 4.6, p's <.001) than whites (ORs=1.7, 1.8, p's <.05) and African-Americans (OR = 1.5, ns; 1.7, p <.05). The unadjusted odds ratios of parental last year marijuana use on child marijuana use among Hispanics were slightly more than twice those of whites and African-Americans for lifetime use and almost three times those for last year use (p's<.05; Wald test). However, the ethnic differences become non-significant with control for sociodemographic covariates (see Chapter 6).

## 5.2.c Extensiveness of Parental Marijuana Use and Child Marijuana Use

Three measures of parental extensiveness of marijuana use were available: total number of days (or times) used lifetime, past year and past month. Because of the relatively small number of parents who were using within the past month, the analysis of children's marijuana use as a function of the extensiveness of very recent parental use could only be exploratory.

The format of the frequency of lifetime use varied across survey years. In particular, the highest number of days used was expanded from a maximum of 100+ to 200+ and then to 300+ (see Technical Appendix). Since children's use did not vary as a function of these three categories (Table A.5.12), a four-category variable was used across the 10 surveys, where 100+ was the highest category. Percentages of children's using marijuana as a function of extensiveness of parental use and odds ratios are displayed in Table 5.6. There is a slight trend for the percentages of marijuana using children to increase as a function of extensiveness of parental use. However, none of the differences were statistically significant. There were no significant variations in children's lifetime or last year use by extensiveness of parental use. The high odds observed for the missing category among parents who used marijuana in the last year remains to be explained, especially since these missing cases were structurally missing and did not reflect any self-selection bias on the part of participants in the survey.

While we expected parental influence to vary as a function of recency and extensiveness of use, no such effects were found. Overall parental influence is moderate. As will be seen in the next chapter, the odds between parental and child marijuana use increase when other factors are controlled, in particular child and parent age.

In 1979, 1982, 1988 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.
For parent-child dyads, adjusted estimates based on the 1991 distribution of child age for 12-17 and 18-25 year olds.
Age ranges for dyad parents are 24-73, 27-80 and 31-74; and for non-dyad parents 26-87, 26-71 and 26-71, for children aged 12-14, 15-17 and 18-25, respectively.
Differentiation of children aged 12-14 and 15-17 not available for non-dyad parents in 1979 and 1982.
Estimates of dyad and non-dyad parental marijuana use for 12-14 and 15-17 year olds excludes the 1979 and 1982 surveys; estimates for 12-17 year olds includes all survey years. Data for 18-25 year olds available in NHSDA 1991-1996.

# CHAPTER 6: PARENTAL MARIJUANA USE AND OTHER PREDICTORS OF MARIJUANA USE AMONG CHILDREN

## 6.1 Introduction

Three analyses were implemented to examine the nature of parental influences on their children's marijuana use. The first analysis investigated the effect of parental membership in the baby boom generation on offspring marijuana use. Two additional multivariate analyses investigated the influence of parental marijuana use on the drug use of their children, controlling for other covariates, and identified other significant predictors of child marijuana use. One set of analyses examined the effects of parent and child characteristics in logistic regression models. The final set of analyses estimated structural equation models to specify the direct and indirect paths of selected parental and child variables on child marijuana use.

# 6.2 Parental Exposure to the Marijuana Epidemic

A basic question underlying this research was to what extent did parental membership in the baby boom generation account for the sharp increase in the prevalence of marijuana use observed among adolescents in the 1990s. To answer this question, we developed a typology of differential parental exposure to the marijuana epidemic that took into account exposure to different incidence and prevalence rates in late adolescence. As described in Chapter 2, we identified five historical periods of the marijuana epidemic and nine different types of exposure among the parental cohorts. These exposure types classified parental birth cohorts according to exposure to these five periods, i.e., whether parents spent their adolescent years in historical periods prior to or after the marijuana epidemic or in periods characterized by different combinations of low or high incidence and prevalence rates. Because of the very small sample size in exposure type #9, groups #8 and #9 were combined. Offspring marijuana use was examined as a function of parental membership in cohort types and parental drug use.

Since rates of marijuana use vary with age, descriptive data about the ages and rates of parental and children use in the eight cohorts types are presented in Table 6.1. Parent age ranged from a mean of 47.3 years to a mean of 28.5 years across the cohorts, and child age ranged from a mean of 15.8 to a mean of 12.8 years. Parental lifetime prevalence of use was very low in the oldest cohorts, increased sharply in the second oldest cohorts, who reached adolescence prior to the marijuana epidemic and in a period of low incidence; prevalence rates increased gradually in successive cohorts, peaked in the cohorts that experienced both high incidence and high prevalence, and declined gradually thereafter. By contrast, the rates of parental last year use increased gradually in the first six cohorts and stabilized in the two youngest cohorts. The rates of lifetime and last year used among the children decreased across the eight parental cohorts, in part because the children were younger.

We examined the four associations between parental lifetime and last year use with child lifetime and last year use. The association between parent last year use and child lifetime use was examined to assess whether parents who continued to use marijuana in their thirties, at a time when the majority of users have stopped using, would have a greater impact on their children than parents who were no longer using marijuana. Unadjusted odds ratios and odds ratios adjusted for parent and child age are presented for the four combinations of parent and child lifetime and last year marijuana use in Table 6.2. The odds of child lifetime and last year use were more likely to be statistically significant for parental lifetime than last year use, and for older than younger cohorts. The odds for the aggregated baby boom cohorts (#2-#7) were not significantly different from those for the pre-baby boom generation cohorts (#1). We also examined the differences for all the pair-wise comparisons among the cohorts. There were variations among cohorts within the baby boom generation. In three of the four combinations of parent and child use the odds for the four oldest cohorts (#1-#4), including the pre-baby boom cohort, were higher and significantly different from those in the younger cohorts (#5, #6 or #7). The exception was parental lifetime use on child last year use. Cohorts could be classified into two groups: cohorts in the pre-baby boom and early periods of the baby boom generation, showing higher levels of parental influence; cohorts in the late phase of the baby boom and post baby boom, showing lower levels of influence. The difference between the two groups of aggregated cohorts was significant for parent last year use on child lifetime use. Unexpectedly, the odds were significantly lower among parents who experienced high incidence (Group #5) or a combination of high incidence and high prevalence in their adolescence (Group #6) than among preceding cohorts. We expected parents who spent their adolescence in the period of greatest exposure to marijuana use incidence and prevalence to have the strongest influence on their children. Differential censoring in children's opportunities to initiate marijuana use across parental birth cohorts could partially explain these results. Parental birth cohorts who experienced both high incidence and prevalence (1960-62) were among the youngest in the sample ( $\bar{x}$  age =32.5 years) and therefore had younger children ( $\bar{x}$  age = 13.6 years) than earlier parental birth cohorts (child \(\infty\) age range from 14.2 to 15.8 years). The youngest adolescents were even less likely than the older ones to have gone through the entire period of risk for initiation of marijuana use.

In a final test of the baby boom hypothesis, we examined the effect of the interactions between birth cohort and parent lifetime (Table 6.3) and last year (Table 6.4) marijuana use on the child marijuana use. This provided a more definitive test of whether, given a specific type of parental marijuana use history, parents from different birth cohorts would have differential influence on their children. The interaction term was significant only for parental last year use on child lifetime use (p<.03) (Table 6.4). This significant interaction effect reflected the cohort specific patterns described above, in which the highest similarity between parent and child was observed for the three oldest birth cohorts (1946-1956).

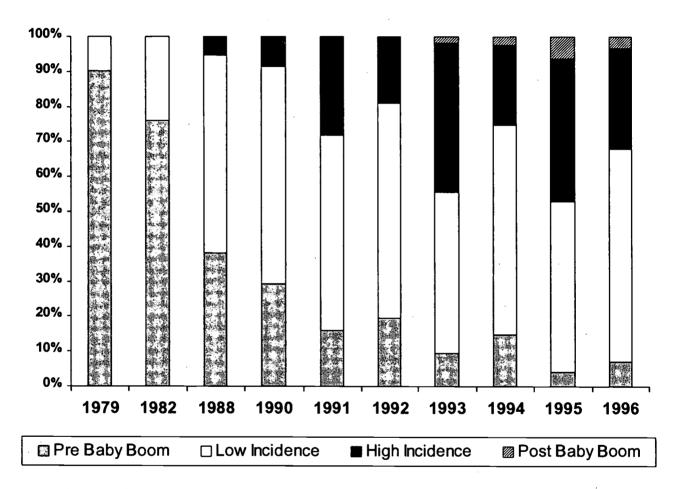

A major hypothesis of the study was not confirmed. Parental membership in the baby boom generation did not appear to account for the differential rates of children's marijuana use, even though parents born between the years 1946 and 1964 used marijuana at higher rates than parents born before 1946 or born after 1963. Association in marijuana use between parents and children did not vary according to parental membership in the baby boom cohorts, who experienced different periods of low and high marijuana use prevalence or incidence in their youth. There was no effect of parental birth cohort with control for ages of child and parent and for the relationship of marijuana use in the cohorts. [Footnote #1]. Futhermore rates of use among children of parents born between 1946 and 1964 were lower than for parents born before 1946; and rates of use among children of parents born between 1946 and 1964 were similar to those of parents born after 1964. The lack of effect of parental membership in baby boom cohorts on children's marijuana use is illustrated in Figures 6.1 and 6.2. Figure 6.1 shows the distribution of birth cohorts among parents of children aged 12-17 in NHSDA surveys from 1979 to 1996 by the level of marijuana use incidence parents experienced in their youth. Parents who experienced high incidence of marijuana use constituted an increasingly larger proportion of parents in the years 1991-1996. However, as shown in Figure 6.2 marijuana use among parents and adolescents diverged and were mirror images of each other in that same period. Lifetime marijuana use rates among parents of youths and young adults approximately doubled from 1979 to 1994, reflecting the increasing dominance of the baby boom cohorts among parents. However, most of this increase occurred during the 1980's, a period in which youth and young adult drug use rates were declining. During the period of rapid increase in youth marijuana use (1992 to 1995), the percent of parents who were baby boomers or who had ever used marijuana did not change enough to have been a major factor in the youth increase. [Footnote #1- Similar correlations between parental and child marijuana use, when rates of parental use vary across birth cohorts, may not be reflected in parallel variations in children's rates of use, since other factors than parental use affect the child's use. The regressions that we estimated controlled for a limited number of relevant factors and provided adjusted estimates of parental effects.

We investigated which factors in addition to parental marijuana use accounted for child marijuana use.

# 6.3 Predictors of Marijuana Use

Child's lifetime and last year marijuana use were regressed on selected predictors. A limited number of potential predictors were available in the NHSDA and their availability varied across surveys. Due to this variability in the availability of measures, models were estimated on three different samples of aggregated surveys to analyze the largest sample for each combination of predictors. The analyses based on the more restricted samples allowed the inclusion of several individual characteristics found in prior research to predict the use of marijuana by young people (for review, see Hawkins et al., 1992). We chose not to include an interaction term between parental cohort and marijuana use in the multiple regression models including other covariates because of the reduced sample sizes in these analyses.

- (1) The 1979-1996 comprehensive aggregate sample, consisted of all the surveys and included the most restricted number of covariates. Only parent and child sociodemographic characteristics (i.e., family intactness, ethnicity, gender, education), parent lifetime, past year and extensiveness of marijuana use, use of other substances (i.e., cigarettes, alcohol, cocaine), and child drop out status were specified in the models.
- (2) The 1991-1994A aggregate sample added parent and child attitudinal and personal characteristics, including parent and child delinquency, perceived risk of occasional marijuana use, and two sociodemographic characteristics, household income and population density.
- (3) The 1994B-1996 aggregate sample included, in addition to the variables listed in (1) above, individual characteristics not included in (2): parent depression and anxiety, child behavioral and emotional problems, as well as two sociodemographic variables included in (2) above: household income and population density. Parent and child delinquency were not available in 1994B and 1996, and perceived risk of marijuana use was not available in 1995 and could not be included in the 1994B-1996 aggregate models.

Each model was estimated five times for each sample to assess the impact of five different measures of parental marijuana use on offspring use. The measures distinguished currency and extensiveness of use: marijuana use lifetime, last year use versus former use, frequency of lifetime use, frequency of past year use, and frequency of past month use. There were too few cases of past month use, especially frequent past month use, to provide stable estimates. These models are presented in Tables A.6.10 and A.6.11. To the extent possible, the definitions of the three other drug variables included in each model (cigarettes, alcohol, cocaine) were the same as for marijuana. However, this strategy could not be implemented with respect to frequency of lifetime and last year use for alcohol and cigarettes, either because this information had never been obtained or had been obtained only in selected years. For these two drugs, the former past year user variable was included in the lifetime frequency of marijuana use model, and the past month frequency of use variable was included in the past year frequency of marijuana model. Because the frequency of past year cocaine use was very low, the former/past year use classification was included instead in the frequency of past year marijuana model.

Since the effects of covariates other than drug use were very similar across models for child lifetime and last year use, only one set of results for these variables predicting lifetime use from lifetime parental marijuana are presented and discussed in this chapter (Table 6.5). Exceptions to the general pattern are mentioned. When patterns for lifetime and last year child marijuana use are the same, we usually refer to child marijuana use. Results for the four parental drug use variables included in each set of models are presented for child use lifetime (Table 6.6) and last year (Table 6.7) to facilitate comparison of coefficients based on different measures of drug use. The full models for each parental drug use parameterization and child lifetime and last year use are presented in Tables A.6.2-A.6.11.

One important point needs to be noted before examining the effects of specific covariates. The overall effect of parental marijuana use on the child *increased* when parent and child sociodemographic covariates and child dropout status were included in the models. The adjusted odds ratio of parental lifetime use on child lifetime use was 2.75 compared with an univariate odds ratio of 1.61 (Panel A, Table 6.6). The comparable odds ratios of parental last year use on child last year use were 2.55 and 1.71 respectively (Panel A, Table 6.7). However, compared with Panel A, the adjusted odds ratios declined somewhat when personal parent and child characteristics were controlled for, in addition to the sociodemographic variables.

Sociodemographic characteristics. Of the parent and child sociodemographic characteristics that were examined, many were associated, although weakly, with child lifetime (Panel A, Tables 6.5; A.6.2, A.6.4, A.6.6, A.6.8, A.6.10) and last year (Panel A, Tables A.6.3, A.6.5, A.6.7, A.6.9, A.6.11) marijuana use. Several of these relationships had been noted in the earlier discussion of descriptive data on the epidemiology of drug use in the dyads (Chapter 4). The strong univariate effect of parental birth cohort shows striking reductions with control for sociodemographic characteristics (Page 1, Tables 6.5; A.6.2-A.6.11). Adolescent males were more likely than females to use marijuana (Page 2, Tables 6.5; A.6.2-A.6.11), and whites were more likely than African-Americans to use marijuana only in their lifetime (Page 1, Tables 6.5; A.6.2, A.6.4, A.6.6, A.6.8, A.6.10). Marijuana use increased gradually with age, peaked between ages 19-21, and declined thereafter. Children from more recent birth cohorts, those born between 1970 and 1984, were less likely to use marijuana than those born between 1962-1964 (Page 2, Tables 6.5; A.6.2-A.6.11). Sociodemographic and structural characteristics of the family affected child marijuana use. Compared with children in intact families, children in widowed families were more likely to use marijuana lifetime and last year; while those in divorced families were more likely to use in the last year only (Page 1, Tables 6.5; A.6.2-A.6.11). Children in mother-child dyads were more likely to use marijuana than those in father-child dyads. Higher levels of parental education were associated with higher rates of child last year and to a lesser extent lifetime marijuana use. Living in the Western region of the United States was associated with the highest rates of adolescent marijuana use, living in the Southern region with the lowest. Household income had no impact on child marijuana use (Page 1, Tables 6.5; A.6.2-A.6.11).

Child personal characteristics. Child personal characteristics, including behavioral and emotional problems, delinquency and attitudes toward marijuana use predicted child marijuana use (Panels B and C, Table 6.5; Tables A.6.2-A.6.9). The coefficients were generally higher for child last year than lifetime use, probably because these predictors were measured within the last year. The most significant predictor was attitude regarding the risks involved in using marijuana. Children who perceived little or no physical risk associated with occasional marijuana use were nine times as likely to use marijuana in their lifetime and 12 times as likely to use in the last year compared with children who perceived that occasional marijuana use posed great risk (Panel B, Tables 6.5; A.6.3). Because of the cross-sectional nature of the data, the causal relationship between use and attitudes cannot be specified. Whether attitudes precede use, or whether behavior leads to more favorable drug-related attitudes remains to be determined.

Child delinquency (Panel B, Tables 6.5; A.6.2-A.6.11) and behavioral problems (Panel C, Tables 6.5; A.6.2-A.6.11) were significantly associated with marijuana use. For the continuous delinquency variable the AOR for last year use was 1.6, and for the dichotomous behavior problems the AOR was 4.1. Child emotional problems (i.e., withdrawal, anxiety and somatic complaints) were associated with lifetime marijuana use but not for last year use (Panel C, Tables 6.5; A.6.2, A.6.4, A.6.8, A.6.10).

Although very few adolescents in the sample had dropped out of high school (5.3%), those who did were almost three times as likely to use marijuana as non drop-outs (adjusted AORs=2.2-3.3) (Tables 6.5; A.6.2-A.6.11).

Parent Characteristics. In contrast to the predictive strength of child personality characteristics, parent personality characteristics, including major depression, anxiety problems and delinquency in the past year, did not predict child marijuana use. Parental marijuana attitudes predicted only child lifetime marijuana use in the univariate models. Without control for other factors, children's lifetime marijuana use was slightly higher (UOR= 1.5, p<.05) when parents perceived that occasional marijuana use posed little or no physical risk than when parents perceived great risk (Panel B, Tables 6.5; A.6.2, A.6.4, A.6.6, A.6.8).

Parental use of marijuana and other drugs. Unique effects of parental use of marijuana and use of other drugs on child lifetime and last year marijuana use were present (Tables 6.6, 6.7; A.6.2-A.6.11). Parental marijuana use, irrespective of the time frame of the measure, was significantly and uniquely associated with child marijuana use, controlling for other covariates, including parental use of other drugs. Parents who had used marijuana in their lifetime but were not current (last year) users and those who reported using marijuana within the last year had children who used marijuana at similar rates. Although the odds of child lifetime marijuana use were slightly higher (AOR=3.7) when parents had used marijuana more than 200 days in the past year compared with parents who had used 200 or fewer days (AOR=2.7) (Panel A, Table 6.6; A.6.8), the difference was not statistically significant (See Table 6.7 for child last year use.)

Parental use of other drugs significantly predicted child marijuana use. Parental use of cigarettes, alcohol, and cocaine, as well marijuana, each uniquely predicted child lifetime and last year marijuana use (Tables 6.6, 6.7; A.6.2-A.6.11). As we had observed for parental marijuana use, with rare exceptions, former and past year use of these three other drugs had similar associations with child marijuana use. Without control for personal characteristics, current parental drinkers had a stronger effect on the child marijuana use than former drinkers. Former and past use of cigarettes and cocaine were equally associated with child marijuana use. Extensiveness of drug consumption in the last year was not associated with increased rates of child marijuana use. A puzzling association was observed between frequency of parental smoking and child smoking (Panel C, Tables 6.6, 6.7; A.6.8-A.6.11): the *lowest* odds were observed among the *heaviest* smokers, who smoked more than 35 cigarettes a day. The low prevalence of parent last year cocaine use prevented the estimation of the effect of last year frequency of cocaine use. Percentages of children using marijuana as a function of parental use of cigarettes, alcohol and cocaine are presented in Table A.6.1.

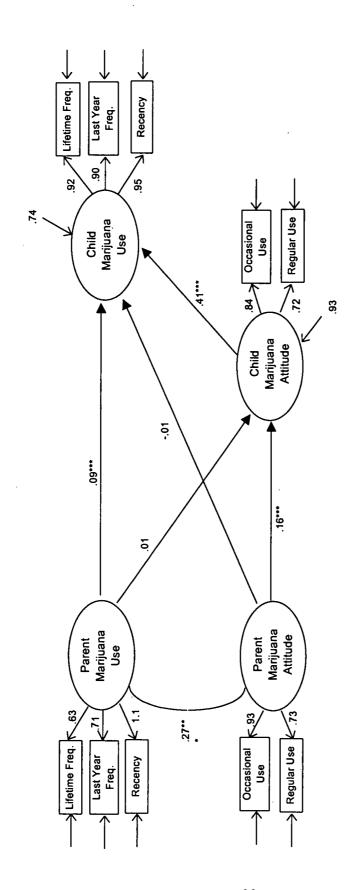

# 6.4 The Role of Attitudes Toward Marijuana

Given the importance of adolescent marijuana attitudes as a correlate of marijuana use, analyses were undertaken to explore the effects and determinants of these attitudes, especially in relationship to parental marijuana use and attitudes. These analyses were restricted to the 1991-1994A aggregated surveys, where data about child attitudes as well as delinquency were available.

Structural equation models were estimated to specify the direct and indirect paths of influence of selected parental and child variables on child marijuana use. Two structural models were estimated. The first model examined the direct impact of parental marijuana use, parental marijuana attitude and child marijuana attitude on child marijuana use as well as the impact of parental attitude on child attitude. Child attitude and use were endogenous variables (Figure 6.3). The second model added exogenous variables for parental use (cigarette, alcohol, cocaine), two indicators of child deviance (delinquency and being a school drop out), and age (Figure 6.4). With the exception of age, school drop out and child delinquency, which were represented by manifest indicators, the remaining constructs were represented by latent variables. The paths for child age are not shown. (The correlation matrix is presented in Table A.6.12)

<sup>1</sup> Child age is included in the model; paths are not shown.

Source: SAMHSA, Office of Applied Studies, National Household Survey on Drug Abuse.

The simpler structural model (Figure 6.3) elucidates the direct and indirect effects of parental marijuana use and attitudes on child marijuana use and attitudes. Parental effects on the child are present across the same domain, from parental behavior to child behavior, or from parental attitude to child attitude. There are significant direct effects of parental marijuana use on child marijuana use, and of parental marijuana attitudes on child marijuana attitudes, but no direct cross-over effects of parental marijuana behavior on child marijuana attitudes and of parent marijuana attitudes on child marijuana behavior. As was noted in the logistic regression models, there is a very strong and significant direct path from child marijuana attitudes to child marijuana use. This effect is by far the strongest path in the model. There is a significant indirect effect (.05, p<.001) of parent marijuana attitude on child marijuana use mediated through child marijuana attitude, but no direct effect. As a further exploration of the consequences of membership in the baby boom generation, we examined parental marijuana attitudes in each of the eight types of birth cohorts. We expected parents in the baby boom generation to have more favorable attitudes toward marijuana than other cohorts. Perceived risks associated with occasional and regular use were examined (Table 6.8). There was a decline in perceived risk from the oldest to the youngest cohorts, with similar rates for five of the intermediate cohorts. This downward trend may be related to the decreasing age of cohort members rather than to type of exposure to the marijuana epidemic.

The preeminence of child marijuana attitude was retained in the more comprehensive model (Figure 6.4). Attitude was the strongest predictor in the model and was five times as strong as parental use. The next most important predictor was child delinquency. Its association with marijuana use was four times as strong as the association between adolescent and parental use. In addition to its direct effect on use, delinquency also had an indirect effect through the child attitude (.08, p<.001), for a total effect of (.33, p<.001). The same pattern was observed with respect to being a school drop out, although the size of the path was smaller. Of the four parental drug use factors, marijuana and cigarette use had the same effect. The effect of cocaine was slightly lower. There was no direct effect of alcohol use on the child marijuana use, but an indirect effect through its impact on the child marijuana related attitude. Surprisingly, this was the only one of the four substances to impact on the child attitude, after controlling for the use of other drugs.

The most striking results presented in this chapter pertain to the importance of children's marijuana related attitudes on their marijuana use and the importance of parental use of drugs other than marijuana in addition to parental marijuana use.

To assess the substantive implications of the results, predicted changes in rates of adolescent marijuana use were estimated from assumed changes in parental behaviors and attitudes and youth attitudes. Coefficients obtained in Figure 6.4 were used to calculate these estimates.

<sup>1</sup> Child age is included in the model; paths are not shown. Correlations among exogenous variables not shown. Source: SAMHSA, Office of Applied Studies, National Household Survey on Drug Abuse.

Effect of parental marijuana use on child marijuana use

For a one-unit decrease in parental last year marijuana use, e.g., from 1-2 days a year to not using at all, 7 out of 100 youths would reduce their marijuana use by one level, e.g., from using marijuana 6 times a month to using marijuana 3 times a month.

Effect of parental marijuana attitude on child marijuana use

For a one-unit decrease in favorableness of parental attitudes toward marijuana use, e.g., from moderate to great perceived risk of occasional use, 4 out of 100 youths would reduce their marijuana use by one level, e.g., from using marijuana 6 times a month to using marijuana 3 times a month.

Effect of parental marijuana attitude on child marijuana attitude

For a one-unit decrease in favorableness of parental attitudes toward marijuana use, e.g., from moderate to great perceived risk of occasional use, 13 out of 100 youths would increase their perceived harmfulness of marijuana use by one unit, e.g., an increase from moderate to great perceived risk of occasional use.

Effect of child marijuana attitude on child marijuana use

For a one-unit decrease in favorableness of youth attitudes toward marijuana use, e.g., from moderate to great perceived risk of occasional use, 36 out of 100 youths would reduce their marijuana use by one level, e.g., from using marijuana 6 times a month to using marijuana 3 times a month.

As we noted earlier, in the absence of longitudinal data, the causal relationship between young people's marijuana attitudes and use cannot be determined. However, at any point in time, the association of use with attitude is the strongest of any other factor that was examined.

# **CHAPTER 7: CONCLUSION**

Several findings are noteworthy. The most important is the relatively small size of the univariate effects of parental marijuana use on the child's marijuana use. The average unadjusted odds ratios of the association between child and parental marijuana use were 1.6-1.7. Odds ratios adjusted for parent and child sociodemographics increased to 2.8. Lifetime and last year marijuana use of the older children 18 to 25 years old tended to be as highly and in some cases more highly associated with parental last year marijuana use than did use by younger children 12 to 17 years old. Most of the parental effects appeared to be those of lifetime use, and did not depend either on recency or extensiveness of use. The lack of variation suggests that the influence of parental marijuana use on children's use does not result primarily from role modeling of the parent by the child. There were no statistically significant differences in parental effects between mothers and fathers, and sons and daughters.

The hypothesis regarding the impact of parental membership in the baby boom generation on offspring marijuana use was not confirmed. There was no systematic effect of membership in the baby boom generation on children's marijuana use. Although there were differences in patterns of influence within the baby boom cohorts, the cohorts who experienced the highest levels of exposure to the marijuana epidemic had the lowest levels of influence on their children. Pre-baby boomers were similar to the oldest baby boom cohorts.

It is important to keep in mind that the conclusions of this report are affected to some extent by the fact that known important predictors of adolescent marijuana use, particularly peer drug use, could not be taken into account in the analysis.

The most important findings are summarized below.

- Parental membership in the baby boom generation (1946-1964 birth cohorts) did not account for the differential rates of children's marijuana use.
- Lifetime marijuana use rates among parents of youths and young adults approximately doubled from 1979 to 1994, reflecting the increasing dominance of the baby boom cohort among parents. However, most of this increase occurred during the 1980's, a period in which youth and young adult drug use rates were declining.
- During the period of rapid increase in youth marijuana use (1992 to 1995), the percent of parents who were baby boomers or who had ever used marijuana did not change enough to have been a major factor in the youth increase.

- Parental lifetime and last year marijuana use increased the risk that a child would ever use marijuana. Controlling for parent and child sociodemographic characteristics, the children of parents who ever used marijuana were about three times as likely to have ever used marijuana as the children of parents who never used the drug. With additional control for attitudinal and behavioral characteristics, the risk declined to about two.
- Parents who stopped using marijuana and those who were currently using marijuana had children who used marijuana at similar rates (e.g., 22%-27% lifetime use). This suggests that parental influence does not reflect imitation of the parent by the child but the effect of the parent having chosen to become a marijuana user.
- The influence of parental marijuana use on child lifetime marijuana use was similar for mothers and fathers, and sons and daughters.
- Parental influence on child marijuana use did not vary among racial/ethnic groups, after controlling for parent and child characteristics.
- Parental use of cigarettes, alcohol and cocaine each independently increased the risk that a child will use marijuana over and beyond the influence of parental use of marijuana.
- Parents who perceived little risk associated with marijuana use had children with similar beliefs. In addition, parental attitudes had an indirect effect on the child's use through the child's own attitudes.
- Adolescent attitudes had the strongest association with adolescent marijuana use of any of the three adolescent characteristics that were examined. Adolescents who perceived no risk or slight risk in occasional marijuana were twelve times more likely to have used marijuana in the last year than adolescents who perceived great risk.
- The association between adolescent marijuana use and attitudes about the lack of harm associated with marijuana use was five times as strong as the association between adolescent and parental use.
- Adolescent delinquency had a strong association with adolescent marijuana use and attitudes about the lack of harm associated with marijuana use.
- The association between adolescent delinquency and marijuana use was four times as strong as the association between adolescent and parental use.

- Adolescents who dropped out of school were significantly more likely to use marijuana than nondropouts.
- Externalizing behavioral problems (e.g., aggression, delinquency) were more strongly associated with adolescent marijuana use than were internalizing problems (e.g., anxiety, depression).
- Sociodemographic characteristics, including ethnicity, parental education and marital status, were weakly associated with adolescent marijuana use.
- Predicted changes in rates of adolescent marijuana use were estimated from assumed changes in parental behaviors, parental attitudes and adolescent attitudes.
  - If 100 parents reduced their marijuana use from 1 to 2 days a year to not using at all, 7 adolescents would decrease their marijuana use from 6 times to 3 times a month.
  - If 100 parents changed their perceptions about the harmfulness of occasional marijuana use from moderate to great risk, 4 adolescents would decrease their marijuana use from 6 times to 3 times a month.
  - If 100 parents changed their perceptions about the harmfulness of occasional marijuana use from moderate to great risk, 13 adolescents would similarly change their perceptions.
  - If 100 adolescents changed their perceptions about the harmfulness of occasional marijuana use from moderate to great risk, 36 would decrease their marijuana use from 6 times to 3 times a month.

# TECHNICAL APPENDIX: CONSTRUCTION OF DRUG USE AND OTHER VARIABLES

# A.1 Drug Use Variables

The format of the drug use variables varied across the survey years 1979-1996 included in this report. Major changes were introduced in 1988 and 1994B.

# A.1.a Marijuana Use Variables

Parent and child lifetime marijuana use (MRJFLAG). Recoded binary variable was derived from the imputed marijuana recency variable (IRMJRC). The latter was based on the original recency of marijuana use question (MJREC), "When was the most recent time that you used marijuana or hash(ish)?". In 1979, MJREC consisted of eight categories: (91) never used marijuana; (1) used within the past week; (2) used within the past month; (3) used within the past six months; (4) used six months to a year ago; (5) used more than a year ago; (6) used more than two years ago; (7) used more than five years ago. In 1982, five categories: (91) never used marijuana; (1) used within the past month (30 days); (2) used within the past six months (but more than a month ago); (3) used six months to a year ago; (4) used more than a year ago. In 1988 and 1990-1994A, seven categories: (91) never used marijuana; (1) used within the past week; (2) used more than one week ago but less than one month ago; (3) used more than one month ago but less than six months ago; (4) used more than six months ago but less than one year ago; (5) used more than 1 year ago but less than 3 years ago; and (6) used 3 or more years ago. In 1994B-1996: (91) never used marijuana; (1) used more than one week ago but less than one month ago; (2) used more than one month ago but less than 12 months ago; (3) used more than 12 months ago but less than 3 years ago; (4) used 3 or more years ago. For Lifetime marijuana use, category (91) was coded 0=never used; all other categories were coded 1=ever used.

Parent and child past year marijuana use (MRJYRX and MRJYR). For parents, a trichotomous variable (MRJYRX) was derived from the imputed marijuana recency variable (IRMJRC) and original recency of marijuana use question (MJREC). In all survey years, category (91) of IRMJRC was coded 0=never used marijuana; in 1979, categories (5) through (7); in 1982, category (4); in 1988 and 1990-1994A, categories (5) and (6); and for 1994B-1996, categories (3) and (4) were coded 1=former use, not in the past year. In 1979, categories (1) through (4); in 1982, categories (1) through (3); in 1988 and 1990-1994B categories (1) through (4); and in 1994B-1996, categories (1) and (2) were coded 2=used in the past year. For parents and children a binary variable (MRJYR) was also constructed from IRMJRC. For 1979 categories (91) and (5) through (7) were coded 0=did not use marijuana in the past year;

categories (1) through (4) were coded 1=used in the past year. In 1982, categories (91) and (4) were coded 0; categories (1) through (3) were coded 1. In 1990-1994B, categories (91), (5) and (6) were coded 0=did not use in the past year, and categories (1) through (4) were coded 1. In 1994B-1996, categories (91), (3) and (4) were coded 0; categories (1) and (2) were coded 1.

Parent frequency of lifetime marijuana use (MJTOTX). Recoded, based on the original variable MJTOT. In 1979 and 1982, five categories: (91) never used marijuana; (1) used 1 or 2 times lifetime; (2) used 3-10 times lifetime; (3) used 11-99 times lifetime; (4) used 100 or more times lifetime. In 1988 and 1990-1994A, eight categories: (91) never used marijuana lifetime; (1) used 1-2 times lifetime; (2) used 3-5 times lifetime; (3) used 6-10 times lifetime, (4) used 11-49 times lifetime; (5) used 50-99 times lifetime; (6) used 100-199 times lifetime; (7) used 200 or more times lifetime. In 1994B-1996, six categories: (91) never used marijuana; (1) used more than 300 days; (2) used at least 101 but not more than 30 days; (3) used at least 12 but not more than 100 days; (4) used at least 3 but not more than 11 days; (5) used at least 1 but not more than 2 days. Recoded to 4 categories (MJTOTX). In all survey years category (91) was coded 0=never used marijuana; in 1979 and 1982 categories (1) and (2); in 1988 and 1990-1994A categories (1) through (3); and in 1994B-1996 categories (4) and (5) were coded 1=used 1-10 times/days lifetime. In survey years 1979 and 1982 category (3); for 1988 and 1990-1994A categories (4) and (5); and in 1994B-1996 category (3) was coded 2=used 11-99 times/days lifetime. In 1979 and 1982 category (4); in 1988 and 1990-1994A categories (6) and (7); and in 1994B-1996 categories (1) and (2) were coded 3=used 100 or more times/days lifetime.

Parent number of days used marijuana in the past 12 months (MJYRFRQX). Four category recoded variable based on the imputed marijuana frequency variable (IRMJFQ). The latter was based on the original eleven-category frequency of use question (MJYRFREQ), "How often in the past 12 months have you used marijuana?" In 1988 and 1990-1994A: (91) never used marijuana; (93) did not use marijuana in the past 12 months; (1) used several times a day in the past 12 months; (2) used daily in the past 12 months; (3) used almost daily in the past 12 months; (4) used 1 or 2 days a week in the past 12 months; (5) used several times a month in the past 12 months (25 to 50 days); (6) used 1 to 2 times a month (12 to 24 days) in the past 12 months; (7) used every other month or so (6 to 11 days) in the past 12 months; (8) used 3 to 5 days in the past 12 months; and (9) used 1 to 2 days in the past 12 months. In 1994B-1996, selected response categories changed slightly. Categories (91), (93) and (5) through (9) did not change; category (1) became used more than 300 days in the past 12 months (5 to 6 days a week); category (2) used 201 to 300 days in the past 12 months (5 to 6 days a week); category (3) used 101 to 200 days in the past 12 months (3 to 4 days a week); and category (4) used 51 to 100 days in the past 12 months (1 to 2 days a week). Category (91) was coded 0-never used marijuana; category (93) as 1=former use, not in the past 12 months; categories (3) through (9) as 2=used 1-200 days in the past 12 months; and categories (1) and (2) as 3=used 201 or more days in the past 12 months. Available in 1988 and 1990-1996.

Parent number of days used marijuana in the past thirty days (MJDAY3OX). A four category variable based on the original continuous variable, "Number of days used marijuana/hashish in the past 30 days (MJDAY3OA): (91) never used marijuana; (0) no use in the past 30 days; (1) through (30) for days used in the past 30 days. Recoded: 0= never used marijuana; 1=former use, not in the past 30 days; 2=used 1-10 days in the past 30 days; 3=used 11-30 days in the past 30 days.

# A.1.b Other Drug Use Variables (Cigarettes, Alcohol, Cocaine)

Parent lifetime cigarette use (CIGFLAG). Recoded binary variable derived from the imputed cigarette recency variable (IRCIGRC). The latter was based on the original recency of cigarette use question (CIGREC), "When was the most recent time you had a cigarette?" In 1979 and 1982 five categories: (91) never used cigarettes; (1) used in the past 30 days; (2) used within the past six months; (3) used within the past year; (4) used more than a year ago. In 1988, 1990-1994A: (91) never used cigarettes; (1) used within the past month; (2) used more than one month ago but less than 6 months ago; (3) used more than six months ago but less than one year ago; (4) used more than 1 year ago but less than 3 years ago; (5) used 3 or more years ago. In 1994B-1996: (91) never used cigarettes; (1) used within the past month; (2) used more than one month ago but less than one year ago; (3) used more than one year ago but less than three years ago; (4) used 3 or more years ago. Category (91) was coded 0=never used cigarettes; all other categories were coded 1=ever used.

Parent past year cigarette use (CIGYRX). Trichotomous variable (CIGYRX) derived from the *imputed* cigarette recency variable (IRCIGRC) and original recency of cigarette use question (CIGREC). In all survey years, category (91) was coded 0=never used cigarettes; in 1979 and 1982, category (4); in 1988 and 1990-1994B, categories (4) and (5); and in 1994B to 1996, categories (3) and (4) were coded 1=former use, not in the past year. In 1979 and 1982, category (4); in 1998 and 1990-1994A, categories (1) through (3); and in 1994B-1996 categories (1) and (2), were coded 2=used in the past year.

Parent smoked at least 100 or more cigarettes in lifetime (CIG5PKX). Variable used only in the structural equation model for survey years 1991-1994A. Recoded variable based on the original three category variable (CIGS5PK): (91) never used cigarettes; (1) smoked 100 or more cigarettes in lifetime; (2) did not smoke 100 or more cigarettes in lifetime. Categories (91) and (1) were recoded (CIG5PKX) to: 0=never used cigarettes or did not use 100 or more cigarettes in lifetime; category (2) to 1=used 100 or more cigarettes in lifetime.

Parent number of cigarettes per day in the past 30 days (CIGMFRQX). Recoded five category variable (CIGMFRQX) based on the original eight category daily quantity of use question variable "Number of cigarettes smoked per day in the past 30 days" (AVCIG). (81/91) never used cigarettes; (93/99) did not smoke cigarettes in the past 30 days; (1) smoked less than one cigarette per day; (2) smoked 1-5 cigarettes per day; (3) smoked 6-15 cigarettes per day; (4) smoked 16-25 cigarettes per day; (5) smoked 26-35 cigarettes per day; (6) smoked 36 or more

cigarettes per day. Category (91) was coded 0=never used cigarettes; category (93/99) as 1=former use, not in the past 30 days; categories (1) through (3) as 2=smoked 1-15 cigarettes per day; categories (4) and (5) as 3=smoked 16-35 cigarettes per day; category (6) as 4=smoked 36 or more cigarettes per day.

Parent number of cigarettes smoked daily (PACKSX). Variable used only in the structural equation model for survey years 1991-1994A. Six category recoded variable, number of cigarettes smoked per day as a daily smoker (PACKS): (91) never smoked cigarettes; (1) smoked 1-5 cigarettes per day; (2) smoked 6-15 cigarettes per day; (3) smoked 16-25 cigarettes per day; (4) smoked 26-35 cigarettes per day; (5) smoked 35 or more cigarettes per day. For analytical purposes category (91) was recoded to 0; all other categories remained the same.

Parent lifetime alcohol use (ALCFLAG). Recoded binary variable derived from the imputed alcohol recency variable (IRALCRC). The latter was based on the original recency of alcohol use question (ALCREC), "How long has it been since you last drank an alcoholic beverage?" In 1979, eight categories: (91) never used alcohol; (1) used within the past week; (2) used within the past month; (3) used within the past six months; (4) used six months to a year ago; (5) used more than a year ago; (6) used more than two years ago; (7) used more than five years ago. In 1982, five categories: (91) never used alcohol; (1) used within the past month; (2) used within the past six months; (3) used six months to a year ago; (4) used more than a year ago. In 1988 and 1990-1994A, six categories: (9) never used alcohol; (1) used within the past month; (2) used more than one month ago but less than 6 months ago; (3) used more than six months ago but less than one year ago; (4) used more than 1 year ago but less than 3 years ago; (5) used 3 or more years ago. In 1994B-1996, five categories: (9) never used alcohol; (1) used within the past month; (2) used more than one month ago but less than one year ago; (3) used more than one year ago but less than 3 years ago; (4) used 3 or more years ago. Category (9) was coded 0=never used alcohol; all other categories were coded 1=ever used.

Parent past year alcohol use (ALCYRX). Trichotomous variable (ALCYRX) derived from the *imputed* alcohol recency variable (IRALCRC) and original recency of alcohol use question (ALCREC). In all survey years, category (9) of IRALCRC was coded 0=never used alcohol. In 1979, categories (5) through (7); in 1982, category (4); in 1988 and 1990-1994A categories (4) and (5); and in 1994B-1996, categories (3) and (4) were coded 1=former use, not in the past year. In 1979, categories (1) through (5); in 1982, categories (1) through (3); in 1988 and 1990-1994A, categories (1) through (3); and in 1994B-1996, categories (1) and (2) were coded 2=used in the past year.

Parent frequency of past year alcohol use (IRALCFQX). Variable used only in the structural equation model for survey years 1991-1994A. Imputed variable, based on the nine category variable (IRALCFQ): (1) used daily in the past year; (2) used almost daily in the past year; (3) used 1-2 days per week in the past year; (4) used several times a month in the past year; (5) used 1-2 times a month in the past year; (6) used every other month in the past year; (7) used 3-5 times in the past year; (8) used 1-2 times in the past year; (9) never used alcohol or did not

use in the past year. Categories (9) through (1) were recoded from low to high use (IRALCFQX): 0=never used alcohol to 9=used daily in past the year.

Parent number of times very high or drunk on alcohol in the past 12 months (DRUNKYRX). Variable used only in the structural equation model for survey years 1991-1994A. Recoded ten category variable (DRUNKYRX) based on the original eleven category variable (DRUNKYR): (1) got very high or drunk daily in the past 12 months; (2) got very high or drunk three to six days a week in the past 12 months; (3) got very high or drunk one or two days a week in the past 12 months; (4) got very high or drunk 25-51 days in the past 12 months; (5) got very high or drunk 12 to 24 days in the past 12 months; (6) got very high or drunk 6 to 11 days in the past 12 months; (7) got very high or drunk 3 to 5 days in the past 12 months; (8) got very high or drunk 1 or 2 days in the past 12 months; (9) did not get very high or drunk in the past 12 months; (91) never used alcohol; (93) did not use alcohol in the past 12 months. Categories (91) and (93) were coded 0; categories (9) through (1) were reverse coded from low to high use: 1=did not get very high or drunk in the past 12 months.

Parent quantity/frequency of alcohol use in the past 30 days (ALCMFRQX). Categorical variable derived from the frequency of alcohol use variable (ALCDAYS), "On about how many different days did you have one or more drinks of beer, wine or liquor during the past 30 days?", and the number of alcohol drinks per day in the past 30 days variable (NODR30A), "About how many drinks of beer, wine or liquor did you usually have in a day on the days that you drank during the past 30 days?" A continuous measure of current average daily alcohol intake (average number of drinks per day) was the product of the frequency of days drank in the past month (ALCDAYS) and number of drinks consumed per day (NODR30A), divided by 30. Four categories were derived: 0=never used alcohol; 1=former use, not in the past 30 days; 2=used less than 2 drinks per day in the past 30 days; 3=used 2 or more drinks per day in the past 30 days. Available in 1988 and 1990-1996.

Parent lifetime cocaine use (COCFLAG). Recoded binary derived from the imputed cocaine recency variable (IRCOCRC). The latter was based on the original recency of cocaine use question (COCREC), "When was the most recent time that you used cocaine, in any form"? In 1979, seven categories: (9) never used cocaine; (1) used within the past week; (2) used within the past month; (3) used within the past six months; (4) used six months to a year ago; (5) used more than 1 year ago; (6) used more than 2 years ago; (7) used more than 5 years ago. In 1982, five categories: (9) never used cocaine; (1) used in the past month; (2) used in the past six months; (3) used six months to a year ago; (4) used more than a year ago. In 1988 and 1990-1994A, seven categories: (91) never used cocaine; (1) used within the past week; (2) used more than 1 week ago but less than 1 month ago; (3) used 1 or more months ago but less than 6 months ago; (4) used 6 or more months ago but less than a year ago; (5) used 1 or more years ago but less than 3 years ago; (6) used 3 or more years ago. In 1994B-1996 five categories: (9) never used cocaine; (1) used within the past 30 days; (2) used more than 30 days ago but within the past 12 months; (3) used more than 12 months ago but within the past 3 years; (4) used more

than 3 years ago. In all survey years, category (9) was coded 0=never used; all other categories were coded 1=ever used.

Parent past year cocaine use (COCYRX). Trichotomous variable (COCYRX) derived from the imputed cocaine recency variable (IRCOCRC) and recency of cocaine use question (COCREC). In all survey years, category (9) of IRCOCRC, was coded 0=never used. In 1979, categories (5) through (7); in 1982 category (4); in 1988 and 1990-1994A categories (5) and (6); and in 1994B-1996, categories (3) and (4) were coded 1=former use, not in the past year. In 1979, categories (1) through (4); in 1982 categories (1) through (3); in 1988 and 1990-1994A categories (1) through (4); and in 1994B-1996 categories (1) and (2) were coded 2=use in the past year.

Parent frequency of lifetime cocaine use (COCTOTX1 and COCTOTX2). Two variables were constructed. a four category version for the logistic regression models and an eight category version for the structural equation models. In 1979 and 1982, four categories: (91) never used cocaine; (1) used 1 or 2 times; (2) used 3 to 10 times; (3) used 11 to 99 times; (4) used 100 or more times. In 1988 and 1990-1994A, eight categories: (91) never used cocaine; (1) used 1 or 2 times; (2) used 3 to 5 times; (3) used 6 to 10 times; (4) used 11 to 49 times; 95) used 50 to 99 times; (6) used 100 to 199 times; (7) used 200 or more times. In 1994B-1996, six categories: (91) never used cocaine; (1) used more than 300 days; (2) used at least 101 but not more than 300 days; (3) used at least 12 but not more than 100 days; (4) used at least 3 but not more than 11 days; (5) used at least 1 but not more than 2 days.

In the four category version (COCTOTX1), in all survey years, category (91) was coded 0=never used marijuana. In 1979 and 1982, categories (1) and (2); in 1988 and 1990-1994A, categories (1) through (3); and in 1994B-1996 categories (4) and (5) were coded 1=used cocaine 1-10 times/days in lifetime. In 1979 and 1982, category (3); in 1988 and 1990-1994A, categories (4) and (5); and in 1994B-1996, category (3) were coded 2=used cocaine 11-99 times/days in lifetime. In 1979 and 1982, category (4); in 1988 and 1990-1994A categories (6) and (7); and in 1994B-1996 categories (1) and (2) were coded 3=used cocaine 100 or more times/days in lifetime. In the eight category version (COCTOTX2), used only the 1991-1994A surveys, category (91) was coded 0=never used cocaine; all other categories remained the same.

Parent frequency of past year cocaine use (IRCOCFQX). Variable used only in the structural equation model for survey years 1991-1994A. Imputed nine category variable (IRCOCFQ): (9) never used or did not use in the past year; (1) used daily in the past year; (2) used almost daily in the past year; (3) used 1-2 days per week in the past year; (4) used several times per month in the past year; (5) used 1-2 times per month in the past year; (6) used every other month in the past year; (7) used 3-5 times in the past year; (8) used 1-2 times in the past year. Recoded (IRCOCFQX): category (9) was coded 0; categories (1) through (8) were reverse coded from low to high use, 1=used 1-2 times in the past year to 8=used daily in the past year.

## A.2 Other Variables

## A.2.a Sociodemographic Variables

Parent and child education (EDUCCT2X). Recoded variable, five categories. For parents and children aged 18-25, the original response categories for EDUCCT2 were retained: 1=less than high school/dropout; 2=high school graduate; 3=some college; 4=college graduate. For children aged 12-17, the school enrollment (YTHSTUD in 1979 and 1982; ENROLLD in 1988 and 1990-1996) and last grade completed (YTHEDUC in 1979 and 1982; EDUC in 1988 and 1990-1996) variables were used to assign children to one of the four categories of EDUCCT2 or to a fifth category labeled "in secondary school."

Child school dropout (CDRPOUTX). Constructed variable based on the recoded variable EDUCCT2X: 1=less than high school/dropout; 2=high school graduate; 3=some college; 4=college graduate; 5=in secondary school. Categories (2) through (4) were coded 0=not a dropout; category (1) as 1=dropout.

## A.2.b Personal Characteristic Variables

Parent depression in past 12 months (MDE1). Major depressive episode Version 1 based on MDESFS1. Two sets (1 and 2) of parallel questions were used to determine MDESFS1. Respondents were administered either set 1 or set 2 of the depression items. In set 1, ten items were used to construct MDESF1. For item set 1, if a respondent reported near daily or daily feelings of depression (DEPFREQ=1 or 2) that lasted most or all of the day (DEPDAY=1 or 2) for a period of two weeks or more (DEPRESS=1), MDESFS1 was coded 1. Seven additional binary items, the loss of interest (LOSTINT1; 0=no, 1=yes), excessive fatigue (TIRED1; 0=no, 1=yes), gained or lostten or more pounds in the past 12 months (LBSCHNG1; 0=no, 1=yes), frequency of sleeping problems (SLPFREQ1; 0=less often; 1=nearly every or every night), trouble concentrating (CONCEN1; 0=no; 1=yes), feelings of worthlessness (DOWN1; 0=no, 1=yes), and thoughts of death (IDEAT1; 0=no, 1=yes) were summated. Scores for MDESFS1 ranged from 0-8.

For item set 2, nine items were used to construct MDESFS1. If the respondent did not report a two week or greater period of depression, but reported a near daily or daily loss of interest in things (LOSINFRQ=1or 2) for most or all of the day (LOSINDAY=1 or 2) in the past 12 months (LOSTINT2=1), MDESFS1 was coded 1. Six additional binary items (TIRED2, LBSCHNG2, SLPFREQ2, CONCEN2, DOWN2, IDEAT2) were summated. For item set 2, scores for MDESFS1 ranged from 0-7. For item sets 1 and 2, a score of ≥3 for MDESFS1 indicated a major depressive episode: 0=probable non-case; 1=probable case. Available in 1994B-1996.

Parent anxiety in past 12 months (GAD1). Generalized anxiety disorder Version 1 (GADI) based on GADSFS1. If a respondent reported a current period of anxiety (WOREND=2)

93

that has been going on for six months or more (WORMON2) or a past period of anxiety (WOREND=1) that lasted six months or more (WORNOM1) in the past 12 months, and the respondent worried about things that were not likely to happen (WORHAPN1=1 or WORHAPN2=1), that were not serious (WORSERI1=1 or WORSERI2=1), and worried about different things simultaneously (WORDIFF1=1 or WORDIFF2=1), GADSFS1 was coded 1. Six additional binary items, restless when worried (WORREST; 0=no, 1=yes), keyed up or on edge when worried (WOREDGE; 0=no, 1=yes) irritable when worried (WORIRRIT; 0=no, 1=yes), heart pounds/races when worried (WORHEART; 0=no, 1=yes), easily tired when worried (WORTIRED; 0=no, 1=yes), trouble falling asleep when worried (WORSLEEP; 0=no, 1=yes) and feel faint when worried (WORFAINT; 0=no, 1=yes) were summated. Scores for GADSFS1 ranged from 0-7. A score of ≥3 indicated an episode of generalized anxiety disorder: 0=non-probable case; 1=probable case. Available in 1994-1996.

Parent and child delinquency in past 12 months (DELQX). Constructed additive variable based on 12 items: "During the past 12 months, have you" (1) "taken something from a store without paying for it?" (STRSTEAL); (2) "taken money or property that did not belong to you?" (OTHSTEAL); (3) "purposely damaged or destroyed property that did not belong to you?" (DAMAGE); (4) "taken a car that didn't belong to someone in your family without the owner's permission?" (CARSTEAL); (5) "used a weapon, force, or strong arm methods to get money or things from a person?" (FORCEMON); (6) "broken into a house or building to steal something or just to look around?" (BREAKIN); (7) "hit someone or gotten into a physical fight?" (PHYFIGHT); (8) "hurt someone badly enough to need bandages or a doctor?" (HURTBAD); (9) "used a knife or gun or some other thing to get something from a person?" (GUNMONEY); (10) "driven any kind of vehicle while you were under the influence of alcohol or illegal drugs?" (DRUNKDRV); (11) "sold any illegal drugs?" (SOLDDRUG); (12) "done anything else that would have gotten you into trouble with the police if they had known about it?" (OTHDOING). Scores ranged from 0-12. Available in 1991-1994A and 1995.

## **APPENDIX TABLES**

Table A.3.1. Percentage of NHSDA Respondents Aged 12-25 Included in Parent-Child Dyads by Age<sup>1</sup> (NHSDA 1979, 1982, 1988, 1990, 1991, 1992, 1993, 1994A, 1994B, 1995, 1996)

<sup>1</sup> In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.

<sup>2</sup> Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

<sup>&</sup>lt;sup>3</sup> Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

<sup>4</sup> Respondents were asked but did not report.

<sup>&</sup>lt;sup>5</sup> For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the

<sup>&</sup>lt;sup>6</sup> Not ascertained for children aged 18-25.

<sup>7</sup> Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. \*p<.05; \*\*p<.01; \*\*\*p<.001, T-test.

<sup>1</sup> In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.

<sup>2</sup> Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

3 Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

4 Respondents were asked but did not report.

<sup>5</sup> For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the reference group.

<sup>6</sup> Not ascertained for children aged 18-25.

1997 Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. \*p<.05; \*\*p<.01; \*\*\*p<.001, T-test.

In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.

<sup>2</sup> Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

<sup>3</sup> Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

4 Respondents were asked but did not report.

For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the reference group.

<sup>6</sup> Not ascertained for children aged 18-25.

7 Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model.

140

In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.

<sup>2</sup> Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

<sup>3</sup> Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

<sup>4</sup> Respondents were asked but did not report.

<sup>&</sup>lt;sup>5</sup> Estimate not calculated because of zero cells.

<sup>6</sup> For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the reference group.

Not ascertained for children aged 18-25.

Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. \*p<.05; \*\*p<.01; \*\*\*p<.001, T-test.

In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected.

Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

Frequency of use is not available for the 1979 and 1982 surveys.

Respondents were asked but did not report. Not ascertained for children aged 18-25.

Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. \*p<.05; \*\*p<.01; \*\*\*p<.001, T-test.

In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected

Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios.

Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

Respondents were asked but did not report.

For Panel C, 1994B-1996, estimate not calculated because of zero cells.

For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the reference group. Frequency of use is not available for the 1979 and 1982 surveys.

Not ascertained for children aged 18-25

Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. p<.05; "p<.01; ""p<.001, T-test.

\* Weighted estimates with SUDAAN PROC LOGISTIC, unweighted N's. OR=Unadjusted odds ratios, AOR=Adjusted odds ratios. In 1979, 1982 and 1990, children aged 12-17 were selected. In all other years, children aged 12-25 were selected

Due to missing cases for parent and child delinquency in the past year, the overall multivariate N is slightly smaller than the univariate N's indicated.

For Panel C, 1994B-1996, estimate not calculated because of zero cells.

Frequency of use is not available for the 1979 and 1982 surveys.

For Panel B, 1991-1994A, child birth cohort 2 is the reference group; for Panel C, 1994B-1996, because of zero cells child birth cohorts 2 and 3 were collapsed as the reference group. Not ascertained for children aged 18-25.

Estimates not calculated in the multivariate model because the missing categories are perfectly collinear with other variable categories specified in the model. \*p<.05; \*\*p<.01; \*\*\*p<.001, T-test Source: SAMHSA, Office of Applied Studies, National Household Survey on Drug Abuse.

### Substance Abuse and Mental Health Services Administration (SAMHSA) Office of Applied Studies **Publications Series**

#### National Household Survey on Drug Abuse (NHSDA) Series:

Reports in the Household Survey Series present information from SAMHSA's National Household Survey on Drug Abuse. This representative survey is the primary source of information on the prevalence, patterns, and consequences of drug and alcohol use and abuse in the general U.S. civilian non-institutionalized population, age 12 and older. This survey has been conducted periodically since 1971 and annually since 1990.

#### "H" Series publications currently available:

National Household Survey on Drug Abuse: Main Findings 1995
The Prevalence and Correlates of Treatment for Drug Problems
Preliminary Results from the 1996 National Household Survey on Drug Abuse
National Household Survey on Drug Abuse: Population Estimates 1996
National Household Survey on Drug Abuse: Main Findings 1996
Preliminary Results from the 1997 National Household Survey on Drug Abuse
National Household Survey on Drug Abuse: Population Estimates 1997
National Household Survey on Drug Abuse: Main Findings 1997
National Household Survey on Drug Abuse: Population Estimates 1998
Summary of Findings from the 1998 National Household Survey on Drug Abuse
National Household Survey on Drug Abuse: Main Findings 1998
Summary of Findings from the 1999 National Household Survey on Drug Abuse

#### Drug Abuse Warning Network (DAWN) Series:

Reports in the DAWN Series provide data on the number and characteristics of (1) drug abuse related visits to a national representative sample of hospital emergency departments, and (2) drug abuse related deaths from selected medical examiner offices. The medical examiner cases are not from a national representative sample. DAWN is an ongoing data system that began in the early 1970's.

#### "D" S

D-17:

Series publ	ications currently available:
D-1:	Drug Abuse Warning Network Annual Medical Examiner Data 1995
D-2:	Mid-Year Preliminary Estimates from the 1996 Drug Abuse Warning Network
D-3:	Year-End Preliminary Estimates from the 1996 Drug Abuse Warning Network
D-4:	Drug Abuse Warning Network Annual Medical Examiner Data 1996
D-5:	Mid-Year 1997 Preliminary Emergency Department Data from the Drug Abuse Warning Network
D-6:	Year-End 1997 Emergency Department Data from the Drug Abuse Warning Network
D-7:	Annual Emergency Department Data from the Drug Abuse Warning Network, 1995
D-8:	Annual Emergency Department Data from the Drug Abuse Warning Network, 1996
D-9:	Annual Emergency Department Data from the Drug Abuse Warning Network, 1997
D-10:	Mid-Year 1998 Preliminary Emergency Department Data from the Drug Abuse Warning Network
D-11:	Year-End 1998 Emergency Department Data from the Drug Abuse Warning Network
D-12:	Drug Abuse Warning Network Annual Medical Examiner Data 1997
D-13:	Drug Abuse Warning Network Annual Medical Examiner Data 1998
D-14:	Mid-Year 1999 Preliminary Emergency Department Data from the Drug Abuse Warning Network
D-15:	Year-End 1999 Emergency Department Data from the Drug Abuse Warning Network
D-16:	Drug Abuse Warning Network Annual Medical Examiner Data 1999

(Continued on next page)

Year-End 2000 Emergency Department Data from the Drug Abuse Warning Network

Mid-Year 2000 Preliminary Emergency Department Data from the Drug Abuse Warning Network

#### Drug and Alcohol Services Information System (DASIS) Series:

Reports in the Services Series provide national and state level data on (1) the characteristics of specialty treatment facilities providing drug and alcohol services; (2) the number of persons in treatment; and (3) the demographic and drug use characteristics of treatment admissions. The Services Series also includes the National Directory of Drug and Alcohol Abuse Treatment Programs. The publications in this Series are based on SAMHSA's Drug and Alcohol Services Information System (DASIS).

#### "S" Series publications currently available:

- S-1: National Directory of Drug Abuse and Alcoholism Treatment and Prevention Programs 1996
- S-2: Uniform Facility Data Set (UFDS): Data for 1995 and 1980-1995
- S-3: Uniform Facility Data Set (UFDS): Data for 1996 and 1980-1996
- S-4R: National Directory of Drug Abuse and Alcoholism Treatment and Prevention Programs 1997
- S-5: National Admissions to Substance Abuse Treatment Services: The Treatment Episode Data Set (TEDS) 1992-1996
- S-6: Uniform Facility Data Set (UFDS): 1997
- S-7: Treatment Episode Data Set (TEDS): 1992-1997
- S-8: National Directory of Drug Abuse and Alcoholism Treatment Programs, 1998
- S-9: Substance Abuse Treatment in Adult and Juvenile Correctional Facilities: Findings from the UFDS 1997 Survey of Correctional Facilities
- S-10: Uniform Facility Data Set (UFDS): 1998
- S-11: Treatment Episode Data Set (TEDS): 1993-1998
- S-12: National Directory of Drug and Alcohol Abuse Treatment Programs 2000
- S-13: Uniform Facility Data Set (UFDS): 1999

#### **Analytic Series:**

Reports in the Analytic Series address special topics relating to alcohol, drug abuse, and mental health. The Analytic Series generally provides data from outcome and other special studies, secondary analysis of multiple data sources, or more in-depth analysis of the data presented in the standard annual reports in the other Office of Applied Studies publication series.

#### "A" Series publications currently available:

- A-1: Employment Outcomes of Indigent Clients Receiving Alcohol and Drug Treatment in Washington State
- A-2: An Analysis of Worker Drug Use and Workplace Policies and Programs
- A-3: Substance Use Among Women in the United States
- A-4: Substance Abuse and Mental Health Statistics Source Book 1998
- A-5: Services Research Outcomes Study
- A-6: Prevalence of Substance Use Among Racial and Ethnic Subgroups in the United States, 1991-1993
- A-7: Analyses of Substance Abuse and Treatment Need Issues
- A-8: Driving After Drug or Alcohol Use: Findings from the 1996 NHSDA
- A-9: The Relationship Between Mental Health and Substance Abuse Among Adolescents
- A-10: Substance Use and Mental Health Characteristics by Employment Status
- A-11: Worker Drug Use and Workplace Policies and Programs: Results from the 1994 and 1997 NHSDA
- A-12: Risk and Protective Factors for Adolescent Drug Use: Findings from the 1997 National Household Survey on Drug Abuse
- A-13: Parental Influences on Adolescent Marijuana Use and the Baby Boom Generation: Findings from the 1979-1996 NHSDA

#### **Methodology Series:**

Reports in the Methodology Series address methodological issues concerning data collection systems conducted by SAMHSA's Office of Applied Studies. These reports include studies of new statistical techniques and theories, survey methods, sample design, survey instrument design, and objective evaluations of the reliability of collected data.

#### "M" Series publications currently available:

- M-1: Substance Abuse in States and Metropolitan Areas: Model Based Estimates from the 1991-1993 NHSDA--Methodology Report
- M-2: Drug Abuse Warning Network Sample Design and Estimation Procedures--Technical Report
- M-3: Development of Computer-Assisted Interviewing Procedures for the NHSDA
